The fellows of Eton and Winchester form the governing body. The fellows of Trinity College, Dublin, who are divided into senior and junior fellows, are elected after examination, and hold the position for life. King's College, London, and some other colleges, have fellows, but their duties are rather different from those at the older universities. Following this use, fellow is used for a member of a learned society. *See* University.

**Felo de se** (late Lat. *felo*, evil doer, i.e. slayer; *de se*, of himself). English legal term, meaning a man who commits a "felony against himself"—in other words, a suicide. A suicide used to be buried, as Thomas Hood puts it, "at four cross roads, with a stake in his inside." This ended in 1823, and the body of a suicide was ordered to be buried in the usual burial-ground without divine service, between 9 p.m. and midnight. In 1882 the night burial was abolished and a religious service permitted; but the burial service of the Church is not allowed by the rubrics to be used. *See* Suicide.

**Felony.** Class of crime in English law. By common law all crimes are either felonies or misdemeanours. Nobody knows for certain the original distinction between them; one theory is that a felony was originally a crime involving a breach of the king's peace. Certainly until 1870 the lands and goods of a felon were forfeited to the crown.

It is a crime to conceal a felony—misprision of felony—but not to conceal a misdemeanour. When a felony has been committed a private person may arrest without a warrant anyone he reasonably suspects of having committed it. A constable may arrest without a warrant a person he reasonably suspects of having committed a felony even if it transpires that none has been committed. With

some few exceptions no such powers of arrest exist in the case of a misdemeanour (*q.v.*).

**Felsite.** Close-grained or compact rock of varying colour. It consists of altered lava which has lost its glassy structure. Small crystals of feldspar and quartz are scattered through the ground-mass of the rock. *See* Rhyolite.

**Felspar.** Variant spelling of name of a group of rock-forming minerals, described in this Encyclopedia as feldspar.

**Felsted School.** English public school. It was founded in 1564 by Richard, Lord Riche, and is now governed by a scheme dating from 1876. It consists of six senior houses of fifty boys each, and a junior house of eighty boys. The grounds are 55 acres in extent. There are at least nine entrance scholarships each year. The village of Felsted, sometimes spelt Felstead, is 3 m. S.E. of Dunmow, Essex, on the railway. Pop. 1,845.

**Felt.** Kind of cloth which properly consists of fibre aggregates, compacted by heat, rubbing, and moisture, and is not woven. (Needlefelts consist of fibres consolidated on to a central coarse hessian cloth.) The pressed felt industry uses wool as its raw material, with rabbit and other animal hairs in some hat felts. The fibres are scoured and well blended, then passed through a carding process to produce a web. These webs are superimposed to form "batts" 40 yds. long, between  $\frac{1}{2}$  in. and 1 in. thick, and 36-80 ins. wide. These are again superimposed to give a thickness of between 6 ins. and 3 ft.

The hardening process follows, the fibre mass being compressed between two metal platens, with a pressure of 5 to 10 lb. per sq. in. Steam is blown in through perforations in the lower platten, and the upper platten has an oscillating movement. By this means a batt 3 ft. thick becomes reduced to 4 ins. The partly-felted batt is then filled, i.e. soaked in soap solution (for felt hats) or dilute sulphuric acid (for mechanical pressed felts) and subjected to blows from heavy wooden hammers. Five minutes' treatment suffices for light felts, but 12 hrs. or more is required for thick mechanical felts. Shrinkage of 25-75 p.c. occurs in all directions during fulling. The resulting felt is scoured, dried, pressed, and loose hairs are sheared off. The complete process takes 7-10 days.

Needlefelts are used for carpet underlays and packaging of a variety of materials. Roofing felts are

impregnated with bitumen and other substances to make them impervious to water. Knitted felts, i.e. knitted wool fabric subjected to a fuling process till it resembles felt externally, have been used for hats, etc. Clement of Rome was commemorated by hatters as the inventor of felt. See Hat.

**Feltham.** An urban district of Middlesex, England, comprising the parishes of Feltham, Hanworth, and Bedfont. It is 12 m. W.S.W. of London, with a rly. station. Large industries in the area include aircraft, plastics, and the making of sparking plugs and fire extinguishers. Hanworth air park and part of London (Heathrow) airport are in the district. Pop. est. 42,000.

**Feltmakers' Company.** London city livery company. Originally an offshoot of the Mercers,

Feltmakers' Company arms

and later (in 1501) of the Haberdashers, it was granted a separate charter by James I in 1604. An Act of Parliament had been passed in 1566 instituting a seven-year apprenticeship for all journeymen feltmakers, of whom there were 7,000 in London at the time of the charter. The authorised livery is now 350. The offices are at Arundel House, Arundel Street, W.C.2.

**Felton, JOHN** (c. 1595-1628). English assassin. He came of a good Suffolk family, early entered the army, and served as lieutenant at Cadiz in 1625. Failing to obtain a captain's commission, he applied personally to the duke of Buckingham, who refused his request. Poverty and his animosity against Buckingham, increased by brooding over the attacks on the king's favourite, turned his thoughts to assassination, and he mortally stabbed the duke at Portsmouth, Aug. 23, 1628. He was hanged at Tyburn, Nov. 28 of the same year.

John Felton, English assassin  
From an old engraving

**Feltre** (anc. *Feltria*). City of Italy, in the prov. of Belluno. A picturesque place, standing on an eminence near the Piave river, 885 ft. above sea level, it is 34 m. by rly. N.W. of Treviso. It has a ruined castle, a cathedral, a mod-

ern palace, and a municipal pawnshop, said to be the oldest establishment of the kind in Europe. Minor buildings include a hospital, gymnasium, seminary, and an asylum for orphans. In 1819 the bishopric was incorporated with that of Belluno. There is trade in wine, oil, and silk. Pop. 19,000.

**Felucca** (Arab. *fuluka*; Ital. *feluca*). Vessel used in the Levant

Felucca. Egyptian sailing boat on the Nile above Cairo

and on the Nile. It is propelled by lateen sails and oars, and moves swiftly. Sometimes the helm can be used at either end of the hull.

**Felup** or **FULUP**. Collective name applied by Portuguese traders to numerous primitive negro tribes in the coast-lands of French Senegal and Portuguese Guinea. Under the Mandingan name Jola they extend into British Gambia. Their allied semi-Bantu dialects prevail from the Gambia and Casamance to the Cacheo and Geba rivers. The typical Felup are muscular, flat-nosed, thick-lipped, dark-bronze-coloured hunters, almost unclad, using bow and arrow and inhabiting roughly constructed log-huts or earth-houses.

**Feme** or **FEMME**. Anglo-Norman legal term for a woman. A woman who is married is called *feme covert*, and a woman who is either a spinster, a widow, or divorced, is *feme sole*.

**Femina Vie Heureuse.** The name of this literary award has been changed to Stock Prize (*q.v.*).

**Feminism** (Lat. *femina*, a woman). Term originally used to signify the qualities of females, employed in 1895 and later to mean the advocacy of the claims and rights of women. Feminism in the second and more usual sense is a century older than the use of the word to describe it, finding its first clear expression in Mary Wollstonecraft's *A Vindication of*

the Rights of Woman (1792). "She set great value on a mutual affection between persons of an opposite sex," wrote her husband, William Godwin, in his memoir of her; "she regarded it as the principal solace of human life." But she also thought that nothing should keep a man and wife together once mutual love and respect had gone. She advocated that women should be educated in an "orderly manner" to fit them to engage in business—"women would not then marry for a support"; that they should become doctors and nurses, and in particular midwives; that they should have "a civil existence in the state, married or single"; that they should not be "arbitrarily governed without having any direct share in the deliberations of government."

In the world into which she projected these ideas, the education of men was indifferent, and of women non-existent; no women and few men had any political rights; married women had no legal existence as individuals, could possess nothing, had no rights in the custody of their children. Both women and men for the most part greeted Mary Wollstonecraft's ideas with ridicule; but some fifty years after her death they began to produce effects, thanks to the help and encouragement given to women by men like F. D. Maurice, John Stuart Mill, Canon Butler, Arthur Hugh Clough, Sidney Herbert, and Newson Garrett.

#### Talfourd's Act

Thomas Noon Talfourd, Whig member of parliament for Reading, and a serjeant-at-law, was responsible for the first step taken in the legal recognition of women's rights as human-beings. Led through disgust at his own success in depriving mothers of access to their children in the course of his legal practice, he secured the passage of an act in 1839 which gave a separated wife custody of her children till the age of seven, and access to them afterwards, provided she could prove she was guiltless of adultery. Maurice promoted the foundation of Queen's College, a school opened in 1848 for the training of governesses—the first school for women that had any claim to a standard of learning.

The first society for female suffrage was formed at Sheffield in 1857, and J. S. Mill brought the subject to general notice by putting female suffrage prominently in his election address in

1866 when he stood (and was returned) for Westminster. The National Society for Women's Suffrage was founded two years later, and in the same year Mill presented the first petition for women's suffrage to Parliament; thereafter petitions were persistently presented and bills brought in, by Mill and others.

Until 1857, divorce was possible only by private act of parliament in each individual case, and only the husband could initiate a divorce bill. In that year an act, promoted by the Attorney-General Sir Richard Bethell (afterwards Lord Westbury), gave both spouses the right to divorce, to the husband for adultery by his wife, to the wife for adultery plus cruelty or desertion by her husband; the same act also gave the wife for the first time legal control of any earnings or inheritance she might acquire after separation. Not until 1870 was the first Married Women's Property Act (*q.v.*) passed: this bill was introduced into the house of commons by Russell Gurney, Q.C., who, with his wife, was also a consistent worker for the advancement of women's education. From these beginnings, increasing rights and responsibilities were demanded in Great Britain for women by both women and men feminists, and steadily devolved upon them. (*See Women's Suffrage.*)

#### Slow Progress on the Continent

Feminism, spreading steadily round the world wherever Protestantism and the Anglo-Saxon way of life held sway, was slow in starting on the continent of Europe. The teaching of Roman Catholicism on marriage hindered its birth in R.C. countries; the Code Napoléon, by giving the wife an inescapable claim on her husband's estate, removed in the countries where it (or its derivative systems) ran one of the bases of feminism in Great Britain.

In tsarist Russia, men and women revolutionaries worked on an equality, and when the revolution came in 1917 equality of status and opportunity was extended to women. Under the Weimar constitution women were given equal political status with men in Germany. In the United Nations Charter the United Nations reaffirmed their "faith in the equal rights of men and women"; and at the end of the Second Great War, women were admitted to the franchise in a number of countries where there had been little or no feminist movement before it (*e.g.*

France, Italy, Hungary). But a movement in the reverse direction had set in: National Socialism deprived German women of the rights they acquired under the Weimar constitution; in Soviet Russia, differentiation in education and opportunity between the sexes was reintroduced in 1943.

Irene Clephane

**Femmes Savantes, LES** (The Learned Women). Five-act comedy by Molière, first acted at the Palais-Royal, Paris, March 11, 1672. In it Molière returns to the theme of feminine affectation less seriously treated in his *Les Précieuses Ridicules*. The easy-going bourgeois Chrysale is at the mercy of a wife and one of his two daughters. The wife has more pretence to learning than knowledge or intelligence, and the elder daughter, Armande, is like her. Clitandre, suitor to Armande, is rebuffed, and turns to her more simple-minded sister Henriette, whom the mother wishes to marry the parlour-poet Trissotin. The *dénouement*, in which Henriette and Clitandre are united, is brought about by Chrysale's brother Ariste, who exposes the mercenary character of Trissotin. Molière acted the part of Chrysale. Trissotin is accepted as a caricature of the Abbé Cotin.

**Femoral Artery** (Lat. *femur*, thigh). Main artery of the thigh running from the groin to a point rather above the knee, where it becomes the popliteal artery and is continued down the leg. It gives off numerous branches, which supply the muscles and skin with blood.

**Femur** or **THIGH-BONE**. Longest bone in the human body. Above it articulates with the pelvis to form the hip-joint, and below with the patella (knee-cap) and tibia to form the knee-joint. The superior extremity consists of a rounded eminence, the head, which fits into the *acetabulum* or socket of the pelvis, the neck, which is set at about an angle of 125° with the shaft of the bone, and two bony prominences known as the greater and lesser *trochanters*, which serve for the attachments of muscles. The shaft of the femur is somewhat convex forwards, and in the central third of the posterior surface bears a prominent ridge, the *linea aspera*, to which muscles are attached. The inferior extremity broadens out into two expansions, the internal and external tuberosities, which end in two smooth rounded articular eminences known as the condyles, separated from each other by a deep depression, the inter-condylar notch.

Fracture of the shaft of the femur is a common accident. If due to indirect violence the fracture is usually oblique; if due to direct violence, more or less transverse. Unless complicated by serious damage to the soft parts, the fracture usually unites in 6 to 8 weeks, though the leg should not be made to bear the full weight of the body for another two months. The two Great Wars saw great advances in treatment of these fractures by mechanical aids. Fracture of the neck of the femur is most often met with in elderly persons, whose bones have become weakened by atrophy. The condition is always serious in aged persons, owing to the difficulty of getting the broken fragments to unite, and to the risk of pneumonia supervening, which is always present when it is necessary to keep an elderly patient in bed for a long time. *See Hip-joint; Knee-joint.*

**Fen.** Anglo-Saxon word for marshy or boggy land. The district of this nature in Cambridgeshire, Norfolk, Huntingdonshire, and Lincolnshire is known as the Fens. The will o' the wisp is sometimes called the fenfire, while fenberry is another name for the cranberry.

**Fence.** Device used on farms for boundary purposes, to prevent stock from wandering and as a wind-screen. The proper establishment and maintenance of fences is costly; they often waste valuable ground, and neglected hedges in particular harbour vermin and weeds, the latter often serving to maintain insect and fungoid pests.

Turf fences, chiefly consisting of mud and stones, are cheap and fairly durable if properly drained and protected from the rain by coping-stones. Walls, usually of the dry sort, without cement or mortar, are much favoured where suitable flat stones are available. They last for many years if carefully built, but after 50 years or more they are liable to get out of plumb, and fall after winter frosts.

Wood and wire fences include a large number of contrivances. These may consist entirely of wood (palings, stakes, brushwood, post and rail), wood and wire, or wire with iron or concrete standards. Wood lasts much longer if treated with creosote or stop-rot composition, or simply tarred. That part of a post driven into the ground should previously be tarred.

As a general rule the owner of land is not bound to erect or maintain a fence at its boundary, but if this is the only method of

preventing his cattle from going on to a neighbour's land, it will be necessary to fence. There is usually no duty to fence land running alongside a highway; even if animals escape on to the highway and cause damage the owner of the land is in general not liable.

There is, however, a liability to fence excavations near a highway and in certain districts to fence land adjoining a street to prevent it becoming a source of danger to passengers or from being used for purposes causing annoyance to the public. Railway companies must make and maintain fences along the side of their railway. Barbed wire must not be used in fences along a highway in such a manner as to be likely to injure persons or animals. By the Barbed Wire Act, 1893, a local authority may compel the occupier of land on which there is a barbed wire fence adjoining a highway to abate the nuisance. One useful kind of wire fencing is rabbit-proof netting.

#### Hedges and Ditches

Hedges are particularly characteristic of many parts of England. They are costly, however, and require continual care. Hedging is an expert rural art, and involves not merely lopping of superfluous twigs and branches, but also "laying" at least every 20 years. In this process the main stems are partly cut through not far from the bottom, bent into an oblique or horizontal position, and then secured. This promotes the growth of shoots at the base of the hedge, without which it will never form a thick continuous stock-proof barrier. Equally important is the provision of a ditch adequately drained, and its maintenance in a clean condition free from weeds and rubbish. The best hedge-plant is the hawthorn (quick), while beech and hornbeam are also good.

**Fenchurch Street.** London thoroughfare. The name is believed to have been derived from the fenny ground in the vicinity when the Langbourne was a running brook. The street runs E. from Gracechurch Street, describing a northward curve until it meets Leadenhall Street at Aldgate Pump. At the London Tavern, rebuilt in 1877, Queen Elizabeth is supposed to have dined in 1554. Shipping companies have their headquarters in the street. Mark Lane and Mincing Lane, on the S. side, are well known in the history of commerce. Fenchurch St. station is the terminus of the line to Tilbury. The street suffered damage in the Second Great War.

**Fencible.** Term applied to regiments of infantry and cavalry raised in Great Britain in the late 18th and early 19th centuries for local defence in time of emergency. Numbers of fencible units were

embodied in 1804 at the time of Napoleon's threatened invasion of England. Later, certain fencible regiments, revived as yeomanry units, were eventually embodied in the Territorial Army (*q.v.*).

## FENCING: ITS HISTORY AND PRACTICE

C. L. de Beaumont, Hon. Sec., Amateur Fencing Association

*The graceful art of swordsmanship, sprung from methods of fighting of great antiquity, achieved a wider popularity as a sport in the course of the 19th century. It is here described in some detail*

The art of swordsmanship is of the greatest antiquity. Fighting with a variety of weapons under set rules was practised among the Persians, Greeks, and Romans. Up to the 15th century, however, swords were heavy and clumsy; it was not until the general disuse of armour led to the transformation of weapons to forms better adapted for speed and neatness that fencing began to develop into an art.

During the 15th century schools and masters of fence grew rapidly in numbers and skill. Germany became the cradle of systematic swordsmanship, and the masters formed guilds such as the famous Marx brüder of Frankfort. Similar associations of professional swordsmen grew up in Spain, N. Italy, and, later, in France. The swordsmanship in these schools was of the rougher kind and many wrestling tricks were used.

The Italians were the first to recognize the superior efficiency of the point and, towards the end of the 16th century, they developed lighter weapons and nimbler and better controlled methods which spread all over Europe and developed into rapier fencing. Fencing masters discontinued the teaching of wrestling tricks, the lunge was discovered, and rapier fencing became an art.

#### The Science of Fencing

The rapier, although well balanced, was too long and heavy for a swordsman to make quick parries with the blade. Body movements, ducking or vaulting aside (*incartata*), were used to avoid thrusts, or the left hand protected with a gauntlet or armed with a dagger was used to parry. Right-hand attacks and left-hand parries were characteristic of rapier fencing.

A scientific system of fencing, based on mathematical lines and diagrams drawn on the floor within a circle, was established in Spain at the beginning of the 17th century.

During the reign of Louis XIV the adoption of the short court sword led to the development of

the French school of small sword fencing which rapidly displaced rapier fencing, the dagger was no longer used, and hits were made with the point only, parries being made with the blade.

Owing to the danger of injury when fencing, various conventions were established and valid hits were restricted to those arriving on the breast; many of these conventions have survived as the basis of the rules of foil fencing.

The invention of the mask by La Boëssière about 1780 permitted the evolution of complicated phrases including remise, counter riposte, and redoublement, and the development of foil fencing as we know it today.

Towards the end of the 19th century épée fencing, approximating to the conditions of a duel, was developed, while the light Italian sabre replaced the heavy military sabre which had continued the tradition of back-swording.

#### Teaching the Art in England

Swordsmanship was taught in England from early times. In 1285 Edward I prohibited fencing schools in London. Swordsmen continued to be regarded with disfavour until Henry VIII granted a royal charter in 1540 to the "corporation of the maisters of the science of defence and other provosts of the same science." The corporation was granted the lucrative monopoly of teaching the art of fencing in England. Sword and buckler and the long (two handed) sword became the traditional English weapons and the rapier was not firmly established here until the latter half of Elizabeth's reign. Public displays of skill with swords were popular amusements in England from the 16th century onwards. Prize fights were displays of swordsmanship until mid-Georgian days when James Figg popularised prize fights with fists. Thereafter backswording became a provincial amusement, and eventually degenerated into singlestick.

Fencing was neglected in England during the Victorian era, and

Fencing. Left; Competitors in the "on guard" position in an International Championship bout at the London Fencing Club. Right; Contestants at practice for the Girls' School Fencing Championship demonstrate that swordsmanship is as graceful an art for women as for men

it was not until the end of the 19th century that the art of fencing was revived, mainly through the enthusiasm of Captain Alfred Hutton. The first amateur championships with foil and sabre were held in 1898, and in 1901 the Amateur Fencing Association was founded. From 1919 to 1939 fencing increased markedly in popularity throughout Great Britain, both for men and women, a large number of championships and competitions were held annually, and British fencers were represented in all the important international meetings including the Olympic games.

Fencing today is practised with three weapons, the foil, the épée, and the sabre. Foil fencing is the basis for the practice of sword play with all three weapons. At foil and épée hits must be made only with the point, at sabre hits are made with the point or with the edge (cuts) or with the first third of the back edge.

#### The Foil and the Sabre

Fencing with the foil and the sabre is subject to the following conventions: (a) the target is limited: at foil, the trunk only, back or front; at sabre any part of the head, arms, or trunk approximately down to the waist; (b) all hits made direct on a part of the body other than the target stop the phrase and annul all subsequent hits; (c) all correctly executed attacks must be parried or completely avoided, and the phrase must be followed through.

Fencing with the épée reproduces, as far as possible, the conditions of a duel: the target includes every part of the fencer, and there are no conventions.

Each weapon consists of a blade and a mounting, which includes

the guard and the handle through which passes the tang of the blade at the end of which the pommel or locking nut is attached. A small cushion is generally fixed inside the guard as a protection for the fingers. The stronger part of the blade, i.e. the part nearest to the guard, is called the forte, while the remainder of the blade is known as the faible.

There are two main varieties of foils and épées — French and Italian. The French weapon has a plain handle and is manipulated by delicate finger work. The Italian weapon has a cross bar and two rings attached to the inner surface of the guard through which the first two fingers are placed, the pommel being strapped to the wrist. Fingerwork is largely

Fencing. 1. Position of hand on foil. 2. Preliminary position. 3. On guard. 4. Lunge. 5. Parry of quarte. 6. Parry of sixte. 7. Parry of septime. 8. Parry of octave. 9. Riposte from parry of quarte

sacrificed to added strength in manipulating the weapon.

Foils usually have bell guards or a double loop guard. Épées have bell guards which may be decentralised to give added protection to the outside of the sword arm. The guard of the sabre is curved to protect the hand from cuts. The flattened point or button of the foil must be covered with waxed thread. A triple steel point (pointe d'arrêt) is fixed to the button of the épée so that hits made on the opponent's clothing shall not glance off. An electrical judging apparatus is used in the major épée events. A martingale (a loop of cord attached to the handle and passed round the fingers) is obligatory to obviate accidents to onlookers if a fencer is disarmed.

Clothing is usually made of light canvas (sail cloth) and must be white. The head is protected by a mask with canvas bib, and a glove or gauntlet is worn on the sword hand. A leather elbow guard should be worn at sabre. Canvas shoes should have leather soles in fencing on a linoleum floor, but rubber soled shoes are preferable on a wooden floor or out of doors. Foil and sabre competitions usually take place indoors on linoleum or cork strips; épée events in the open air on gravel or levelled soil. That portion of the field of play which is used for fencing is called the piste or fencing strip.

In fencing, an attack is made by straightening the arm with the point of the sword threatening the opponent, and lunging. The fencer defends his target by using his weapon to deflect his opponent's blade: this action is called a parry. When an attack is parried the fencer who has parried in his turn straightens his sword arm in order to hit his opponent: this action is called a riposte.

A direct thrust at the target will generally be parried. The real attack is usually preceded by one or more false attacks or feints designed to make the opponent parry too soon so that the attacker may deliver his real attack on some part of the target which his opponent leaves uncovered.

The target (trunk) is divided

by imaginary lines at right angles to each other. One line crosses the centre of the body from left to right; that part of the body above the line is called the high line, that part below is called the low line. The other line passes downwards from the centre of the

Fencing. Target for a right-handed fencer. A left-handed fencer must visualise the diagram in reverse

neck; that part of the body on the sword arm side of this line is called the outside line, that on the other side is called the inside line. (See diagram.)

There are eight parries at foil and épée—two to protect each quarter of the target. The position of the hand in relation to the target when forming some parries are indicated approximately in the drawings in p. 3294. Four of these parries are made with the hand in supination (palm upwards): sixte, quarte, octave, and septime; and four with the hand in pronation (palm downwards): prime, tierce, seconde, and quinte. Parries may be simple, or the opponent's blade may be deflected by a circular movement in the same line called a counter parry.

#### Variety of Attacks

Attacks may be simple, e.g. a direct thrust or a thrust made along the opponent's blade (coulé), a disengagement by passing the blade under the opponent's blade, or a cut-over (coupé) passing over the opponent's blade, or may be made after pressing, beating, or binding the opponent's blade, or may be composed attacks, i.e. preceded by one or more feints or by circular movements called the doublé describing a circle round the opponent's blade when he attempts to counter parry.

There are thus a variety of composed attacks using the movements of simple attacks, attacks on the blade, and the doublé either as feints or for the final movement. Similarly, after an attack has been parried, the riposte may be direct or by disengagement, or may be preceded by one or more feints, etc. The counter-riposte is a riposte made by the original attacker after parrying his opponent's riposte. The remise is the immediate continuation of the attack in the same line after the opponent has parried. When an attack or a riposte is delayed or is

preceded by a number of feints, a stop thrust or time thrust (coup d'arrêt) may be made. Attacks of second intention are then made after drawing the opponent's stop hit or attack and parrying the same, afterwards launching a counter attack.

At épée, the large target and the absence of conventions make it unwise to employ any wide movements such as the cut-over or attacks preceded by a number of feints because such movements expose the attacker to stop hits on the arm. Attacks and ripostes as well as stop and time thrusts tend to be concentrated on the nearest portion of the target, i.e. the opponent's wrist or sword arm. Since double hits count against each fencer, the cardinal rule at épée is to hit your opponent without yourself being hit.

#### Speed and Precision

The épée fencer must develop a sense of timing, judgement of distance, suppleness, speed of footwork, and speed, accuracy, and precision in placing his hits. The flèche attack is a running movement designed to hit the opponent by speed and surprise. It must be exceedingly well timed and requires sound judgement and great precision. Sabre play differs from foil and épée in that the edge is used as well as the point; in choice of time and distance it approximates more to épée than to foil. Simple movements and speed of footwork are essential. There are six parries, and second intention attacks are much used.

Fencing more than almost any other sport has to be learned by actual practice under an instructor. Fencing competitions are judged by a jury consisting of a president, who directs the bout and alone decides on the validity of a hit according to the rules and conventions of fencing and as to the priority between two hits on time at épée, and four judges; two judges watch each competitor and advise the president when a hit is scored on the fencer they are watching.

In individual competitions, the competitors are drawn in pools of six or eight fencers at foil and sabre and eight to twelve fencers at épée. Every competitor fences against every other competitor in the pool in a pre-arranged order of bouts, and the classification is determined according to the number of victories awarded by the president to each fencer.

Teams usually of three to five fencers are drawn against each

other. Every member of one team fences against every member of the other team in a pre-arranged order of bouts. The result is determined by the number of victories (and if necessary the number of hits received and scored) by all the members of each team. Foil and sabre bouts are usually for the best of seven or nine hits. Épée bouts, formerly for one hit, are now usually for the best of three or five hits. The rules of the International Fencing Federation have been adopted by the Amateur Fencing Association for use in Great Britain.

**Fender.** Article of domestic furniture. Used as a guard against the falling of hot cinders from the

mins. at the Oval in 1922, and several times took over 100 wickets in one season. He wrote several books descriptive of international cricket, and was a prolific contributor to the press and a popular broadcaster on cricket.

**Fénelon, FRANÇOIS DE SALIGNAC DE LA MOTHE** (1651-1715). French ecclesiastic, author, and academician. He was born near Sarlat, Aug. 6, 1651. Ordained priest in 1675, he was director of the convent of the Nouvelles Catholiques, and missionary to the Protestants in the disturbed provinces of Poitou and Saintonges, the fascination of his personality, and his mixing of bribery and kindness, being great factors in his success.

boundaries should divide literature, politics, and religion; and his writings cover a wide range. The best

known is the didactic romance, *Les Aventures de Télémaque*, 1699, which, like his *Fables* and his *Dialogues des Morts*, was designed to instruct his

François de Fénelon, French prelate  
After Vivien, Louvre

royal pupil in the conduct of life and the responsibilities of absolute government. His *Éducation des Filles*, 1687, has also a place in the pedagogical literature of the time. Consult *Lives*, Viscount Saint-Cyres, 1906; P. E. R. Janet, Eng. trans. V. Leuliette, 1914.

**Feng-huang-cheng.** Town of N.E. Manchuria, China, in the prov. of Antung. On the Mukden-Antung rly., it was opened to international trade by agreement between China and Japan, 1905. Pop. 51,000.

**Feng-siang.** Town of China, in the prov. of Shensi. It is perched on a high loess terrace on the main road from Peiping to Lanchow.

**Fengtien.** This portion of Manchuria is now the province of Liaoning (*q.v.*).

**Feng-yang.** City of China, in the prov. of Anhwei. It was the birthplace of the Mings, but the first emperor transferred his capital to Nanking.

**Fen-ho.** River of China, in the prov. of Shansi. It is a tributary of the Yellow River.

**Fenianism.** Name given to the revolutionary movement springing from the Fenian brotherhood. Its real name was the Irish Revolutionary Brotherhood. One of the organizers, O'Mahoney, gave it the name of the Fenian Society. This name was derived from the semi-legendary warrior bands (Fianna) of early Irish history. The society was really a political association of Irish and Irish-Americans whose object was to overthrow British government in Ireland and establish a republic there. There was an American branch and an Irish branch. It has been said that the movement began in America, but really the plans for both branches were drawn up in Paris by a band of Irish revolutionaries in 1848.

The Irish famines in the 'forties caused a great emigration to America, and the emigrants laid the blame for their exile on the British government, which had

Fender. Examples in domestic use. Steel and brass fenders of the 18th century  
By courtesy of Gill & Reigate

fire into the room, it came into use upon the introduction of grates raised from the floor, and it superseded the old shallow kerb which enclosed the open stone hearth. The growing popularity of sunken grates and tiled fireplaces in the 20th century has led to a lessening of the need for fenders and a reversion to the shallow curb, usually of tile material, or often no curb at all is used.

**Fender.** Nautical term for a bundle of sticks, rope, or wood dropped over a vessel's side to prevent her from rubbing against another vessel or the wall of a quay. Hence the expression to fend off, *i.e.* to keep away, to protect. A "pudding fender" is a large ball of old rope used as a fender.

**Fender, PERCY GEORGE HERBERT** (b. 1892). English cricketer. Educated at S. George's college, Weybridge, and S. Paul's school, he entered first class cricket in 1910, when he played for Sussex, and by 1914 was a member of the Gentlemen's XI against the Players. He toured Australia with the M.C.C. team in 1920-21 and South Africa in 1922-23. He captained Surrey from 1921 to 1932. Equally useful as a bowler and a fast scoring batsman, Fender made his highest score of 185 in 2 hrs. 10

In 1689 he was appointed preceptor to Louis XIV's grandson, the duke of Burgundy, and in 1695 was made archbishop of Cambrai. Soon after this his interest in quietism and defence of its leader, Mme. Guyon, brought him into collision with his old friend Bossuet, who, after a bitter controversy, obtained the condemnation by Rome (1699) of his offending volume *Explication des Maximes des Saints sur la Vie Intérieure*. Fénelon died Jan. 7, 1715.

Fénelon was a man of great versatility, who did not believe that

Fender (nautical). Left, rope fender in net; right, fender of hazel wood bound with wire

been painfully unsuccessful in its efforts to cope with distress. The sentiment of hatred towards England was fomented by James Stephens and others, who had escaped after the abortive Young Ireland insurrection of 1848. The organizers knew that open rebellion against the armed forces of the British government could bring only disaster, but were persuaded that justice could not be won by peaceful methods. Therefore they held it justifiable to foster "secret warfare"—which those who did not sympathise called outrage and assassination. Their aim was purely political; being neither religious nor agrarian, it appealed neither to the priesthood nor to the peasantry.

Stephens returned to Ireland to organize the society there while the real headquarters remained in America. In the American Civil War, which ended in 1865, numbers of American Irish had learnt the business of fighting. An active secret propaganda was set to work in Ireland; but the authorities seized the offices of "The Irish People," and arrested sundry ring-leaders. In 1866 some hundreds of American Irish attempted to

Fennec. Small fox found in the deserts of North Africa

raise an insurrection in Canada, but failed completely, receiving none of the support expected from the U.S.A. government. Another effort, however, had been prepared in England and Ireland. In Feb., 1867, a plan to seize the arsenal in Chester Castle was forestalled by drafting troops to that city.

In Sept., two Fenians were arrested in Manchester on charges of felony. A rescue was attempted, the prisoners escaped, and a police officer was killed, but 29 Fenians were arrested and three of them were hanged for the murder of the sergeant, which had not been intended, and of which the men convicted had been guilty only in a technical sense. These men

became known as the Manchester Martyrs. A worse crime was the blowing up of a part of Clerkenwell prison on Dec. 13. The brotherhood after this time became merged in other societies of a similar character, such as Clan-na-Gael (*q.v.*), and the Irish Republican Brotherhood. See Ireland, History.

**Fenn**, GEORGE MANVILLE (1831–1909). A British story-writer for boys. He was born at Westminster

G. Manville Fenn, British novelist  
Elliot & Fry

Jan. 3, 1831, and educated at private schools. Having contributed to popular periodicals, he was in 1870 appointed editor of Cassell's Magazine, and in 1873 became proprietor of *Once a Week*. His published work totalled close upon 200 volumes and included numerous stories told in pleasant narrative style, among them being *The Sapphire Cross*, 1871; *The Parson o' Dumford*, 1879; *Off to the Wilds*, 1881; *Nat the Naturalist*, 1883; *Bunyip Land*, 1885; *The Bag of Diamonds*, 1887; *A Crimson Crime*, 1899. Fenn died Aug. 26, 1909.

**Fennec** (*Canis zerda*). Small foxlike member of the dog family, found in N. Africa. The ears are enormously long. The colour is a very pale buff, with white beneath and a black tip to the tail. Fennecs live in burrows in the desert and feed at night on birds, lizards, and small mammals.

**Fennel** (*Foeniculum vulgare*). Tall perennial herb of the family Umbelliferae. It is a native of Europe, N. Africa, and W. Asia. The leaves are much divided into thread-like segments. The tubular but almost solid stem is 3 ft.–4 ft. in height, crowned with compound umbels of minute yellow flowers. The fruits are compressed from side to side. The leaves are used as a pot-herb, and for garnishing dishes, and the fruit supplies an aromatic oil possessing carminative properties.

Fennel. Flower-head and leaf of *Foeniculum vulgare*

**Fenny Stratford**. This town of Buckinghamshire, England, is now part of Bletchley (*q.v.*).

**Fens**, THE. Extensive flat and low-lying region of England, 70 m. in length and

35 m. in extreme breadth, occupying parts of several counties in the neighbourhood of the Wash. They represent the silted up portion of a bay of which only the Wash is left, and systematic drainage at various periods has rendered them extremely fertile. The Romans attempted to drain the Fens by constructing causeways and throwing up immense embankments along the rivers and the seashore, but the sluices were gradually choked and the district again became water-logged, serious inundations by the sea occurring at intervals down to the second half of the 16th century.

In 1634, Francis, earl of Bedford, and thirteen co-adventurers employed a Dutch engineer, Vermuyden, to drain the area now known as the Bedford Level (*q.v.*). It was not until 1807, however, that the effectual draining of the entire region was finally accomplished, the Holland and neighbouring fens having been reclaimed in 1767, the Witham Fens in 1807, and the Welland Fens almost totally reclaimed by 1801. Grain, flax, cole-seed, and potatoes are extensively cultivated, and wild-fowl abound. The Fen country is the home of English skating. During the second half of the 7th century, Peterborough, Ely, Ramsey, Thorney, Crowland, etc., were settled by various monastic orders, who erected churches, monasteries, and abbeys. Great damage was caused by floods in the early spring of 1947.

**Fenton**. This parish of Staffordshire, England, is now part of Stoke-on-Trent (*q.v.*).

**Fenton**, LAVINIA (1708–60). An English actress. She made her first appearance in 1726 as Monimia in Otway's *The Orphan*. Her beauty, voice, and charm soon made her a reigning toast, and her success as Polly Peachum in Gay's *Beckford's Opera* (Jan. 29, 1728) at Lincoln's Inn Fields was such that the opera was played 62 times during the season. The 3rd duke of Bolton married her in 1751. She died on Jan. 24, 1760.

Lavinia Fenton, English actress  
After Hogarth

**Fents** (Fr. *fente*, slit). Remnants of cloth from one yard to a few yards in length. They are too short for sale in a regular way, and are generally sold by weight.

**Fenugreek** (*Trigonella foenum-graecum*). Annual herb of the family Leguminosae. It is a native

Fenugreek. 1. Pea-like flowers. 2. The entire plant

of S. Europe. The leaves are divided into toothed oval leaflets, flowers pea-like, white, on unbranched stems, 1 ft. to 2 ft. high. The plant, whose name means Greek hay, has the odour of new-mown hay, into which it was made by the ancients. The seeds are used in veterinary medicine.

**Fenwick, CHARLES** (1850-1918). British politician. Born at Cramlington, Northumberland, May 5, 1850, he worked on the pit-bank at the age of nine, and on his tenth birthday became an underground labourer. A miner until 1885, he educated himself in his spare time, and held offices under the Northumberland miners' association. He was elected to parliament as Liberal-Labour candidate for Wansbeck in 1885. He was secretary of the parliamentary committee on Trades Unions, 1890, and served on the parl. Coal Dust commission, 1891, and the royal commission on Secondary Education, 1894. He represented Wansbeck until his death, April 22, 1918.

**Fenwick, SIR JOHN** (c. 1645-97). English conspirator. Of an old Northumberland family, he early entered the army. Becoming major-general in 1688, he sat in parliament for his native county, 1677-85. Against William III Fenwick is said to have had an old personal

Sir John Fenwick, English conspirator  
From an engraving

grudge, perhaps reciprocated, and in 1696 he was arrested in connexion with an assassination plot. In his confession he cast aspersions on many prominent Whigs. He was attainted and beheaded on Tower Hill, Jan. 28, 1697.

**Feodor** OR **THEODORE** (1575-98). Tsar of Russia. The son of Ivan the Terrible, he was born

May 11, 1557, and came to the throne in 1584. Mentally deficient, he was never capable of ruling, and was under the direct influence of his brother-in-law, Boris Godunov, who, upon Feodor's death, Jan. 7, 1598, ascended the throne. Another tsar of the same name was half-brother of Peter the Great and was succeeded by him in 1682.

**Feodosia** OR **THEODOSIA**. Town and harbour on the E. coast of the Crimea, U.S.S.R. It lies 70 m. E. of Simferopol and can be reached by rly. from Kerch. The industries are connected with soap, carpets, leather, and caviare. An old colony of Miletus, about 1270 Feodosia became a Genoese emporium, but was taken by the Turks in 1475. Annexed to Russia in 1770, it was developed as a resort. In the Second Great War it was evacuated Nov. 5, 1941; retaken from the Germans Dec. 30; lost to them next month; and regained by the Russian Maritime Army, April 13, 1944.

**Fcoffment**. In England, the common law method of transferring a fee, or freehold. It was a symbolical placing of the transferee in possession of the estate by delivering it to him. If it were a house, the transferor might hand him the key of the front door. If it were land he would hand him, on the land itself, a sod, or a twig, saying, "I liver this to thee in the name of seisin of Whitacre, which is bounded by" (here he would name the boundaries of the estate), "to have and to hold to thee and thy heirs," or for life.

It became customary to set out the boundaries, etc., in a deed on parchment, sealed with the seal of the parties, and then the feoffment was somewhat in this form, "I liver this (sod, twig, etc.) to thee in the name of all the lands set out in this my deed," at the same time handing over the deed, charter of feoffment. The Statute of Frauds (Charles II) made some writing necessary on the sale of land; but livery of seisin or feoffment was still necessary as well. To evade the necessity for feoffment the device was introduced of employing two deeds, (1) a lease to the transferee, and (2) a release to him of the reversion. Neither lease nor release required feoffment. By the Real Property Act, 1845, conveyances of freeholds are made lawful by deed of grant.

**Ferber, EDNA** (b. 1887). American novelist and dramatist. Born at Kalamazoo, Mich., Aug. 15, 1887, she was educated at Appleton, Wis., and at 17 became a

reporter. Beginning her literary career as a short story writer, she achieved her first popular success (in collaboration with G. V. Hobart) with *So Big*, 1924, a representation of American provincial life which won the Pulitzer prize. Her novel *Show Boat*, 1926, dramatised and filmed, had brilliant runs in New York and London; *Cimarron*, 1930, was filmed. In collaboration with G. S. Kaufman she wrote plays notable for their wit and characterisation, which were equally successful as films, e.g. *Dinner at Eight*, 1932; *Stage Door*, 1936. Other books were *Saratoga Trunk*, 1941 (also filmed); *Great Son*, 1945.

**Ferberite**. The iron-rich end-member of the wolframite mineral group. Chemically it is iron tungstate,  $\text{FeWO}_4$ , with subordinate amounts of manganese. See *Wolframite*.

**Ferdinand I** (1503-64). German king and Roman emperor. Born at Alcalá de Henares, Spain, March 10, 1503, he was the younger son of the archduke Philip and of Joanna of Castile. He was thus a Hapsburg, a grandson of the emperor Maximilian and a

Ferdinand I, German king  
After Titian

brother of Charles V. After Charles was chosen emperor in 1519, Ferdinand was given territories in Germany and helped his brother in the work of government. In 1521 he married Anna, daughter of the king of Hungary and Bohemia, and when her childless brother Louis was killed in 1526 he put himself forward as his successor. In both lands he was chosen and crowned; but in Hungary he had for long little more than the name of king.

It is from Ferdinand, not from Charles, that the modern Hapsburgs are descended. The brothers agreed that on the elder's death Ferdinand should succeed him in Germany, leaving to Charles's son Philip only Spain and its colonies. Ferdinand, therefore, was chosen German king in 1531, and when Charles abdicated in 1556 the arrangement was carried out. In the intervening years Ferdinand was fighting for Hungary and dealing as best he could with the religious disorders in Germany and Bohemia. He was useful to Charles after the latter's humiliation at the hands of Maurice of Saxony, and arranged with the Protestants the peace of

Augsburg. His own reign as emperor (1558-64) saw but a continuance of his war with the Turks and of his efforts to settle the religious differences. He died in Vienna, July 25, 1564, his eldest son, Maximilian II, succeeding him.

**Ferdinand II** (1578-1637). German king and Roman emperor. Born at Graz, July 9, 1578, he

Ferdinand II,  
German king

*From an old engraving*

was a son of the archduke Charles and a nephew of he emperor Maximilian II. Educated by he Jesuits, he began his public life as ruler of Styria and Carinthia, the portion of the Hapsburg domains that had been his father's share. His rule was chiefly distinguished for his persecution of the Protestants. In 1612 the emperor Rudolph, Ferdinand's cousin, died, and another cousin, Matthias, became emperor. He was old and childless, and the outcome of much political strategy was the decision that Ferdinand, and not one of his own brothers, should succeed him. The family agreed to the arrangement, and as a beginning the archduke was chosen king of Bohemia and king of Hungary. Matthias died in 1619 and in Aug. his nephew was elected German king.

Meanwhile, in 1618, the Thirty Years' War had begun. A rival to Ferdinand, set up by the Protestants in Bohemia, kindled the flame, and the struggle lasted throughout the emperor's lifetime. Ferdinand acted vigorously, and until the appearance of the Swedes, aided by Maximilian of Bavaria, he was completely victorious. He recovered Bohemia, put an end as far as possible to Protestantism, and by the edict of 1629 gave back lands taken from the Church. The Swedish intervention followed, and in 1635 the emperor made the treaty of Prague with some of his foes. He died Feb. 15, 1637, leaving, by his wife, who was a Bavarian princess, two sons—his successor, Ferdinand III, and Leopold, a prelate. *See* Thirty Years' War.

**Ferdinand III** (1608-57). German king and Roman emperor. Son of the emperor Ferdinand II, he was born at Graz, July 13, 1608. To secure his position his father had him crowned king of Hungary and king of Bohemia during his own lifetime, and in 1636

Ferdinand III,  
German king

he was chosen German king. In 1637 his father died and Ferdinand became the real ruler of these kingdoms and assumed the title of emperor.

The Thirty Years' War, in which he had taken part, was then raging, and his reign saw its end in 1648. He died April 2, 1657, and was succeeded by his eldest surviving son, Leopold I. **Ferdinand** (1861-1948). Tsar of Bulgaria. Born at Vienna, Feb. 26, 1861, he was the youngest son of Augustus, prince of Saxe-Coburg-Gotha, and Clementine, daughter of Louis Philippe. He was well educated, and with his brother Augustus published a book on his botanical observations in Brazil. He entered the Austrian army, but soon his ambition led him in another direction. In 1887 Alexander, prince of Bulgaria, abdicated, and after much intrigue Ferdinand was chosen as his successor. Russia was opposed to him, but he won through and by 1896 most of the objections to him had ceased. In 1908 he proclaimed the independence of Bulgaria, and called himself king or tsar, winning recognition from the powers shortly afterwards. He was an advocate of the Balkan League, and was one of the instigators of the war of 1912-13.

On the outbreak of the First Great War, Ferdinand was cautious enough to await developments before committing himself to any definite policy. His strong German tendencies gradually became more apparent, however, and finally, having exhausted all the prevarications of diplomacy, he declared war, Oct. 13, 1915. He played no conspicuous part in the war itself, and, on the final breakdown of the Bulgarian effort, he abdicated, Oct. 4, 1918, in favour of his son Boris, and retired to Germany. Ferdinand married in 1893 a daughter of the duke of Parma; and in 1908 a princess of Reuss. He died Sept. 10, 1948.

**Ferdinand** (1865-1927). King of Rumania. Born at Sigmaringen, Aug. 24, 1865, he was a son of

Leopold, a member of the non-reigning and Roman Catholic branch of the Hohenzollern family. In 1866 his uncle Charles had been chosen king of Rumania, and as his heir Ferdinand became king in Oct., 1914. The First Great War was then raging, but it was not until 1916 that Rumania joined in on the side of the Allies. The land

was soon overrun by Austro-Germans, and during the difficult period that followed there were rumours of the king's abdication; but these did not materialise, and the end of the war saw him again in possession of his country. He married in 1893 Marie, cousin of George V, and died July 20, 1927.

**Ferdinand**. Name of several kings of Spain and Naples. Other than those who are given separate biographies, the principal are Ferdinand I (d. 1065), El Magno, or the Great, who became king of Castile in 1028; Ferdinand II (d. 1188), king of Leon; and Ferdinand IV (d. 1312), king of Castile. Of the Neapolitan kings, Ferdinand I (1423-94) was the natural son of Alphonso V of Aragon and I of Sicily. He succeeded to the throne by the will of his father. His reign was troubled by the jealousy of the other Italian states, wars with the Turks, and difficulties with France. His grandson, Ferdinand II (1469-96), was temporarily dispossessed by Charles VIII of France. The Bourbon Ferdinand III (1751-1825), king of Sicily, welded the titles of Naples into one and became Ferdinand I of the Two Sicilies.

**Ferdinand III** (1199-1252). King of Castile and Leon, called the Saint. Son of Alfonso IX of Leon and Berengaria of Castile, he succeeded his cousin Henry as king of Castile in 1217, and showed himself a prudent ruler. In 1231 the death of his father brought him the throne of Leon, and as king of Castile and Leon he waged war against the Moors, confining them to Granada, and securing Seville in 1248. He was canonised by Clement X in 1671 on account of his unflinching orthodoxy in representing the Albigenses, and for his services towards the Crusades.

**Ferdinand V** (1452-1516). King of Spain. Known as Ferdinand of Aragon, he was the son of John II, king of Aragon and Sicily, and was

Ferdinand,  
King of Rumania

Ferdinand,  
Tsar of Bulgaria

born March 16, 1452. He was assigned the Sicilian kingdom in 1468, and succeeded his father as Ferdinand II of Aragon in 1479. In 1469 he had married Isabella, sister of Henry IV of Castile, the recognized heiress to the Castilian throne. Henry died in 1474, and Isabella was established as queen of Castile in 1479, the year in which Ferdinand succeeded to the crown of Aragon. There were now in the

Ferdinand V,  
King of Spain

*From a contemp. portrait*

Spanish peninsula five kingdoms: the Moorish dominion of Granada, Portugal, Navarre, Castile, and Aragon. The last two kingdoms were under one crown, though retaining separate governments. A long war with Granada ended triumphantly with its annexation in 1492; and in 1512 Ferdinand acquired almost all of Navarre.

Thus during his reign the entire peninsula, except Portugal, was brought under a single dominion. Sicily was already attached to the kingdom of Aragon, to which S. Italy or Naples was added by the ousting of the French in 1504. Further, the discovery of America, 1492, by Columbus, under the auspices of Ferdinand and Isabella, secured what was almost the monopoly of the New World to Spain, which had thus been raised to the position at least of equality with France. Isabella was something more than the partner of Ferdinand in the expansion of their joint dominion and in bringing each of their separate kingdoms under the effective control of the crown. She rendered ill service to Spain, however, by introducing the Inquisition (*q.v.*) in 1480. The expulsion of the Jews and the harsh restrictions imposed upon the Moors were also highly injurious. The course of future events was greatly influenced by the marriage of the elder daughter Joanna to Philip, duke of Burgundy, heir to the Austrian Hapsburgs, and of the younger, Catherine, to Henry VIII of England, after her betrothal to his brother Arthur, prince of Wales.

Ferdinand was noted as the craftiest sovereign of his day, his only rival in that quality being Henry VII of England, with whom he was usually joined in an alliance in which each sought the maximum advantage at the other's expense. After the death of Isabella, 1504, Ferdinand's craft degenerated

into mere cunning. The crowns of Castile and Aragon were actually parted when Isabella died; but Joanna, duchess of Burgundy, was heiress of both, and her place was taken by her son, afterwards Charles V. Except during a brief interval, Ferdinand retained the government of Castile as regent until his death, Jan. 23, 1516. The character of Ferdinand is summed up in the story of his reply when told that Louis XII complained that he had cheated him once. "He lies: I have cheated him thrice." *Consult History of the Reign of Ferdinand and Isabella*, W. H. Prescott, ed. J. F. Kirk, repr. 1902.

**Ferdinand VI** (1712-59). King of Spain. The second son of Philip V, he was born Sept. 23, 1712, and ascended the throne in 1746. He immediately set himself to carry out internal reforms, having first concluded the peace of Aix-la-Chapelle, 1748. At the outbreak of the Seven Years' War in 1756 he declared his neutrality. Three years later, broken-hearted at the loss of his wife, Maria of Portugal, his reason gave way, and he died Aug. 10, 1759. The crown of Spain passed to his half-brother, Charles III of Naples.

**Ferdinand VII** (1784-1833). King of Spain. Son of Charles IV, he was born Oct. 14, 1784, and five

Ferdinand VII,  
King of Spain

years later became prince of Asturias. In opposition to his father, in 1806 he approached the court of France with the project of marrying one of Napoleon's nieces. He was imprisoned by his father, but the French invasion of Spain caused the latter to abdicate in Ferdinand's favour in 1808. Charles, however, appealed to Napoleon, and withdrew his abdication, and Ferdinand went into retirement. After the Peninsular War in 1814 Napoleon reinstated Ferdinand. A reign of terror followed, and such chaos and rebellion prevailed that in 1823 a French army was sent to establish Ferdinand on his throne. To secure the succession for his daughter, Isabella, in 1830 he abolished the Salic law as applying to the Spanish throne, thus excluding his brother Carlos, an act which led to grave complications later. He died Sept. 29, 1833, and Isabella came to the throne under the regency of Maria Christina. *See* Carlists; Spain; History.

**Ferdinand I** (1751-1825). King of the Two Sicilies. Born in Naples,

Ferdinand I, King  
of the Two Sicilies

Jan. 12, 1751, when his father ascended the Spanish throne as Charles III in 1759, he became his successor as king of Naples and of Sicily. In 1768 he married Maria Carolina of Austria, and was completely dominated by her violent and tyrannical nature.

After the short-lived Parthenopean Republic (1799), in the bloody repression of which Nelson, deluded by Lady Hamilton and Maria Carolina, played a part, Ferdinand oppressed his subjects still more. He aided the Austrians against Napoleon, who sent troops to occupy Naples, whereupon Ferdinand fled to Sicily, and Joseph Bonaparte was proclaimed king in his place. In 1815 Murat, who had succeeded Joseph as king in 1808, was deposed, and Ferdinand returned to vent his spite on the populace by the indulgence of an inconceivable tyranny and cruelty. Uniting Naples and Sicily, he became the first king of the Two Sicilies. At the suggestion of the European powers he promised various reforms, but consistently with the whole tenor of his life he broke all his oaths and repudiated his own signature. He died on Jan. 4, 1825.

**Ferdinand II** (1810-59). King of the Two Sicilies. Born at Palermo, Jan. 12, 1810, he suc-

Ferdinand II, King  
of the Two Sicilies

ceeded to the throne at the age of 20, inaugurating his reign with the promise of many reforms. His despotic and cruel nature soon showed itself, however, and before long the kingdom was groaning under oppression and corruption. The insurrections of 1837, 1843, and 1844 culminated in a rising in Sicily and Naples, 1848, which terrified him into granting a constitution. The crushing of Italian hopes after Novara, 1849, encouraged him to annul this, and in order to quell the revolutionary spirit he caused Messina and Palermo to be bombarded, thus earning the nickname of King Bomba. Those who showed liberal tendencies were imprisoned to the number of about 30,000 under

conditions which Gladstone, who visited the country in 1851, exposed, describing Ferdinand's rule as the "negation of God." He died May 22, 1859.

**Ferdinand** (1769-1824). Grand duke of Tuscany. Born May 6, 1769, he was a younger son of the emperor Leopold II. In 1790, when his father became German emperor, he succeeded to the grand duchy of Tuscany. In 1799 he was deposed by the French, in 1802 was made elector of Salzburg, and in 1806 became grand duke of Würzburg. He was restored to his Tuscan throne in 1814, and by his liberal government saved his people from the misfortunes which overtook their neighbours on the restoration of the old monarchies. He died June 18, 1824.

**Ferentino** (anc. *Ferentinum*). City of Italy, in the prov. of Frosinone. It stands on an eminence at an alt. of 1,290 ft., 43 m. by rly. E.S.E. of Rome. It has extensive remains of the fortifications of the ancient city, including two gateways. It has a fine cathedral with mosaic floors—the aisle was damaged by a shell in the Second Great War—and there are a few Gothic churches. The town trades in oil and wine.

**Ferg**, **FRANZ DE PAULA** (1689-1740). Austrian painter. Born at Vienna, he studied under his father, Pancrazius Ferg, J. Orient, and Jean Graff, and painted landscapes in the manner of Poelenberg and genre in the Flemish style. After some years at the court at Dresden, he visited Brunswick, and then London, where, after enjoying some years of affluence, he died in poverty.

**Ferghana**. Town in Khokand district of Uzbek S.S.R. It lies 10 m. S.E. of Marghelan, in the Ferghana valley, and is reached by branch rly. from Andijan or Khokand. Cotton-growing in the district was expanded in the 1930s, and petroleum wells provide the other main industry. The fertile Ferghana valley yields a variety of fruits, nuts, and herbs. Historically, Ferghana has been the name of a province, which was annexed by Russia in 1876. Pop. of town, pre-war, 35,000.

**Fergus**. River of Eire. It rises in the N.W. of co. Clare and flows generally S. for 25 m. to its estuary at Clare village. The estuary, about 10 m. long and 4 m. in extreme breadth, is dotted with islands and contains salmon.

**Ferguson, ADAM** (1723-1816). Scottish philosopher. Born at Logierait, Perthshire, June 20,

1723, he was educated at Perth and the university of St. Andrews. He became an army chaplain, and was present at Fontenoy with the Black Watch. In 1759 he was chosen professor of natural philosophy at Edinburgh, and retained his post there until 1785, and lived until Feb. 22, 1816. Ferguson is known by his Essay on the History of Civil Society, and the belief in progress towards perfection elaborated in his Institutes of Moral Philosophy, 1772, and Principles of Moral and Political Science, 1792.

**Ferguson, JAMES** (1710-76). Scottish astronomer. Born April 25, 1710, near Rothiemay, Banffshire, he attended Keith

James Ferguson,  
Scottish astronomer  
From a print

g r a m m a r school, but at 10 years old he became a farm hand, and looked after sheep, studying the stars at night. He returned home broken in health, but his ingenious construction of a clock attracted the patronage of Sir James Dunbar. In 1734 he went to Edinburgh, where he painted miniatures. In 1743 he removed to London, and was elected F.R.S. in 1763. He became a popular lecturer on experimental science, but was specially noted as an inventor of astronomical and other instruments. He died Nov. 16, 1776.

**Ferguson, ROBERT** (c. 1637-1714). Scottish conspirator and pamphleteer, known as "the Plotter." Born in Aberdeenshire, he came to England about 1655, and was appointed to the living of Godmersham, Kent, from which he was ejected in 1662 by the Act of Uniformity. He took part in the various plots against Charles II, James II, and William III, but always succeeded in escaping from justice.

**Ferguson, SIR SAMUEL** (1810-86). An Irish poet and antiquary. Born at Belfast, March 10, 1810, and educated at Trinity College, Dublin, he was called to the Irish bar in 1838. Deputy keeper of the public records of Ireland in 1867, he was knighted in 1878. He died

Sir Samuel Ferguson

Aug. 9, 1886. His poems, for the most part metrical versions of Irish legends, comprise Lays of the Western Gael, 1865; Congal, an epic poem, 1872; and a second volume of lays, Poems, 1880. He helped to prepare the way for the Gaelic revival.

**Fergusson, JAMES** (1808-86). Scottish writer on architecture. Born at Ayr, Jan. 2, 1808, he was educated in Scotland, and became a merchant in India, where he made a study of its architecture, his first book on the subject, The Rock-cut Temples of India, being published in 1845. His outstanding work was his General History of Architecture, 1865-76; his non-historical works included The True Principles of Beauty in Art. He died Jan. 9, 1886.

**Fergusson, JOHN MOORE** (1863-1944). Scottish divine. A descendant of Sir John Moore, general at Corunna, he was born at Doune, Perthshire, and educated at St. Andrews and Edinburgh universities. Ordained to Rook Ferry, Cheshire, in 1888, he later served at Woolwich, Southend, Wallington, and Dulwich. He was moderator of the general assembly of the Presbyterian church of England, 1932-33. Fergusson was killed in an air raid, July 4, 1944.

**Fergusson, ROBERT** (1750-74). Scottish poet. Born in Edinburgh, Sept. 5, 1750, he studied at St. Andrews university, and entered the office of the commissary clerk at Edinburgh. In 1771 he began to contribute poems, mostly in the Scottish dialect, for Ruddiman's Weekly Magazine, and these appeared in collected form in 1773. He died Oct. 16, 1774. His work greatly influenced Burns, who in 1789 composed the epitaph for the headstone of his grave in Canon-gate churchyard.

**Feriae**. Sacred festivals or holidays of ancient Rome. The most important were the *Feriae Latinae*, the great Latin festival. During the holding of the *feriae* the city was in charge of special officials and no business was done. See Festival.

**Ferial and Festal**. Terms used in music. In the Christian Church ferial signifies any day not specially observed either as festal or penitential, and the music is of a simpler order on ferial than on festal days.

**Feringhi** (Pers. *farangi*). Corruption of Frank, the name given by Asiatics to a European. It is now used as a term of contempt.

**Fermanagh**. Inland county of N. Ireland. The irregular surface is marked by numerous hills, the

highest of which, wholly within the county, is Belmore (1,312 ft.). Lough Erne consists of two lakes—Upper and Lower—respectively about 15 m. in length and 4 m. in breadth, and about 20 m. in length and at widest about 7 m. in breadth. Upper Lough Erne narrows into two channels round the island on which Enniskillen, the county town, is built. Agriculture is the principal industry. Coal,

integers which will satisfy the equation  $x^n + y^n = z^n$  where  $n > 2$ ) have led to some of the most fruitful developments in number theory. A councillor for the Toulouse parliament, Fermat died Jan. 12, 1665.

**Fermentation** (Lat. *fervere*, to boil). Result of the action of organic substances known as ferments. In 1680 the Dutch microscopist Leuwenhoeck showed that yeast consists of definite globules,

ments are nitrogenous organic substances whose activity is destroyed by high temperatures.

The term ferment was at first applied both to the substances which could be extracted from plant and animal material, and which could break down specific compounds, and also to micro-organisms such as yeasts, bacteria, moulds, etc. Nowadays it is rarely used: micro-organisms are spoken of as ferments, but the term *enzymes* denotes the catalytic substances in all living material.

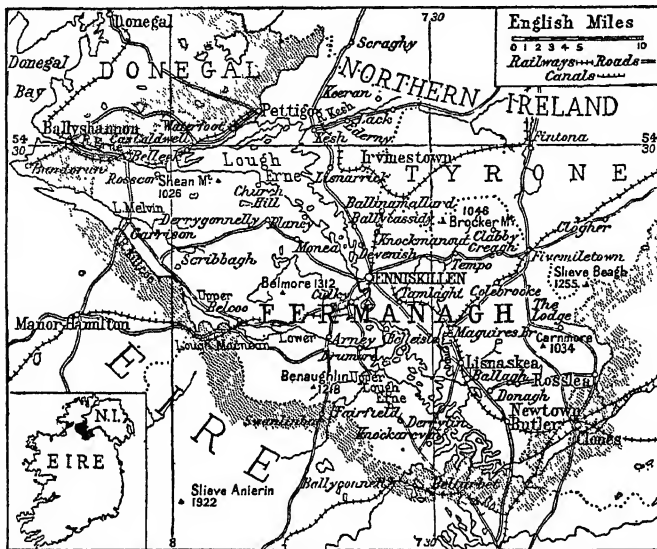

#### **Mucor, Rhizopus, and Penicillium**

At one time any fungal growth on organic material was spoken of as a mould, but in later nomenclature the term was restricted to forms such as *Mucor* (the white mould appearing on damp bread) and the closely related *Rhizopus*, distinguished by its black sporangia; also *Penicillium*, the ubiquitous bluish-green mould present on cheese, jam, bread, etc. *Aspergillus* is often associated with it. The red so-called baker's mould is *Neurospora*. (See Mould.)

**YEASTS.** Also called saccharomycetes because they live mostly in saccharine solutions, converting sugar into alcohol, yeasts form a group of micro-organisms of the greatest importance in fermentation. Yeast cells are round or oval in shape, and multiply by the process known as gemmation or budding, which goes on indefinitely under proper conditions. Otherwise they form spores or new cells liberated by the dissolution of the mother cell.

Although the cells can use oxygen, they appear to be independent of an environment of free oxygen. Time, strength of saccharine solution, and temperature also influence the process of fermentation. The alcohol formed retards the growth of the yeast cell, which ceases to act when above 20 p.c. of alcohol is formed.

Alcoholic or vinous fermentation is the characteristic function of yeasts. Ethyl alcohol (ordinary alcohol) is formed when sugar is fermented. The higher alcohols, propyl, butyl, amyl, and capryl alcohols, are also produced under suitable conditions. Fernbach discovered means of increasing the proportion of amyl alcohol produced during fermentation. Various forms of starch are used as the source of sugar, which is formed by the action of diastase in the process of brewing. Probably all forms are converted into glucose before fermentation proper. (See Alcohol; Rubber.)

Fermanagh. Map of this Northern Ireland county. The inset shows its position in relation to the rest of Ireland.

iron, and building stones are found. Three members are returned to the parliament of N. Ireland, and a joint constituency of Fermanagh and S. Tyrone returns one member to the imperial parliament. Tumuli, raths, castle ruins, and a round tower are among the antiquities. The round tower on Devenish Island in Lough Erne, one of those used as belfries and store-houses for the preservation of monastic treasures during the Danish invasion, with its beautiful carving of the pilaster quoins, retains its original beauty and perfection to a remarkable degree. Area, 653 sq. m. Pop. 54,569.

**Fermat, PIERRE DE** (1601-65). French mathematician, born Aug. 17, 1601, near Montauban. He published nothing in his lifetime, but his posthumous notes on Diophantus enunciated a number of propositions about integers which he claimed to have proved. Proofs for all except the last have since been found, and form the foundation of the modern theory of numbers. Attempts to prove the last (that there are no non-zero

but only in 1836 was it settled that yeast cells originated fermentation.

Latour first observed that the cells were living organisms, and his "vital hypothesis," violently opposed by Liebig, was supported by Pasteur, who in 1857 gave it as his opinion that "the chemical action of fermentation is essentially a correlative phenomenon of a vital act, beginning and ending with it. I think that there is never any alcoholic fermentation without there being at the same time organization, development, multiplication of globules, or the continued consecutive life of globules already formed." In fermentation the amount of matter consumed and changed into other compounds is much greater than the size and weight of the organisms responsible. Yeast globules decompose many times their weight of sugar and produce a relatively large quantity of alcohol and carbon dioxide. Experimental work has thoroughly determined the action of ferments, and also that each particular organism has its special products of fermentation. All fer-

The chief yeasts are: (1) *Saccharomyces cerevisiae*, the ordinary yeast of the brewer and distiller. Two kinds are recognized, "top" and "bottom" yeast, the former rising to the top of the liquid during fermentation and the latter forming a sediment in the vats. Top yeast is used in English ale fermentation, bottom yeast producing the lighter lager beer.

(2) *Saccharomyces ellipsoideus* is the ordinary ferment of vinous fermentation by which "must" or grape juice is converted into wine. (3) *Saccharomyces pastorianus* also occurs in wine-making, and when present during brewing gives a bitter taste to the beer. (4) *Saccharomyces mycoderma* is the cause of "mother" which appears on the surface of wine or beer after exposure for some days to the air.

Hansen, the Danish brewing chemist, isolated and cultivated the two pure yeasts, varieties of *Saccharomyces cerevisiae*, by using which it is possible to obtain beers of distinctive properties.

**ACETIC FERMENTATION.** It has long been known that when wine is exposed to the air it sours—turns into vinegar—and the manufacture of vinegar wort is an old-established art. It is essentially an oxidation process, and Pasteur first detected the organism, "flowers of vinegar," *Bacillus aceti*, which effects the change. Hansen detected two distinct species with the same properties. Both require oxygen for their growth, most favoured by a temperature of 33° C.

Lactic fermentation produces sour milk. The milk sugar is first split up into lacto-glucose and then into lactic acid by the agency of *Bacillus acidilactici*. A special bacillus, named *Bacillus caucasicum*, was found by Metchnikoff to be present in the soured milk called "yoghourt."

Viscous fermentation, due to *Pediococcus cerevisiae*, is the cause of "ropiness" in brewing, and a similar condition in bread-making.

#### Nitrification in Agriculture

Nitrification or the oxidation of ammonia into nitrous and nitric acids takes place through the agency of bacteria. Warington's investigations at Rothamsted showed the importance of nitrification in agriculture. Special preparations of nitrification bacteria are used commercially to promote the growth of leguminous plants.

**ENZYMES** These organic catalysts may be defined as substances produced by living organisms, which initiate or hasten reactions

between organic and inorganic compounds. They are classified according to the class of compounds on which they have effect.

*Esterases* act on carbohydrates and include those acting on complex molecules such as starch, i.e. diastase (almost universally distributed in animals and plants) and cellulose, i.e. cellulases and cytases. True cellulases are found only in a few fungi and bacteria, but cytases occur in most fungi and also in the seeds of many flowering plants and conifers. The commonest enzymes acting on sugars, and thus producing glucose, are invertase and maltase, both widely distributed in plants and animals.

*Lipases* act on fats, converting them into fatty acids and glycerin. The best known is lipase, which is found in the pancreatic juice of mammals and in various plant tissues.

Enzymes affecting proteins are known as *proteolases* and include the coagulating enzymes found in blood and proteolytic enzymes such as pepsin and trypsin (found in animal digestive juices), papain from *Carica papaya*, and a number of enzymes from plant tissues. Proteolytic enzymes assist in the breakdown of proteins into peptones and peptides, and finally into amino-acids.

*Zymase*, from yeast, is a battery of enzymes acting on a variety of compounds.

#### Enzymes in Industry

Enzymes play a part in such industries as brewing and leather making. In the preparation of rubber, the drying of tea, and the curing of tobacco the proper treatment of the vegetable enzymes contained in these substances determines the quality of the products. In drying drugs the activity often depends upon the prompt killing by heat of the enzymes in the plants. Special processes have been evolved in which the vapour of boiling alcohol is employed for this purpose.

**PUTREFACTION.** This is the process of breaking down nitrogenous organic matter, especially proteins, accompanied by the production of evil-smelling gases. The process is due to micro-organisms, the decomposing substances yielding, among other organic bases, methylamine, tri-methylamine, and the important bodies known as ptomaines. Many ptomaines are very poisonous. Produced readily in decaying meat and fish, when introduced into the human body they give rise to serious blood poisoning.

See Brewing; Distilling; Enzyme; Liebig; Pasteur; Yeast.

**Fermi, ENRICO** (b. 1901). Italian physicist. Born at Rome, Sept. 28, 1901, he was educated at Göttingen and Leyden universities, and was appointed to the chair of physics at Florence, 1924, and Rome, 1926. In 1934 he succeeded in breaking heavy uranium atoms into the comparatively small atoms of lanthanum. At the time, however, Fermi imagined that he had merely repeated Rutherford's experiment of chipping small pieces off the atomic nuclei. In 1938 he was awarded the Nobel prize for physics and in 1942 received the Hughes medal of the Royal Society for his research in artificial radio-active substances. Some time before the Second Great War, he went to live in the U.S.A., where he ultimately joined the team of scientists responsible for the atomic bomb.

**Fermo** (anc. *Firmum Picenum*). City of Italy, in the prov. of Ascoli Piceno. It stands on an eminence, rather more than 1,000 ft. high, 4 m. from the Adriatic and 36 m. by rly. S.S.E. of Ancona. Enclosed by battlemented walls, it contains a 13th century cathedral, a town hall, and library, besides remains of Roman buildings. Porto San Giorgio, its port, exports grain, wool, and silk. Fermo was founded by the Romans in 264 B.C. and was a free city from 1199 to 1550, when it fell to the papacy. Pop. 20,000.

**Fermoy.** Urban dist. and market town of co. Cork., Ire. It stands on the Blackwater, 21 m. N.E. of Cork by Eire state rlys. Its importance is chiefly due to the efforts of John Anderson, a Cork merchant, who began to build here in 1791, and later gave a site for the erection of military barracks and founded Fermoy college. The town contains a Roman Catholic cathedral and S. Colman's Roman Catholic college. Salmon and trout fishing is plentiful and a trade in flour is carried on. There are a racecourse and a golf course in the vicinity. Fermoy was the scene of rioting on June 28–29, 1920, when the military wrecked a number of buildings as reprisal for the capture of General Lucas. Market day, Sat. Pop. 9,647.

**Fern** (*Pteridophyta*). A member of the largest and most highly developed group of flowerless plants (Cryptogamia). The *Pteridophyta* include, besides ferns, horsetails, club mosses, and a number of fossil plants. Most are perennial herbs, a few being

shrubby and tree-like, and all possess a well-developed vascular system often of a most complicated net-like nature.

The life history of the Pteridophyta is an example of the so-called alternation of generations in which there are two distinct types of plant, one bearing the sexual organs and the other sporangia. Spores from the latter develop into plants bearing sexual organs whilst the products of sexual fusion develop into spore-bearing plants. The conspicuous fern plant bears on the backs of its leaves small brown patches which consist of innumerable sporangia. When mature these dehisce and scatter hundreds of microscopic spores into the air. If these land on suitably damp soil the spores germinate into small scale-like bodies known as prothallia. The latter bear the sexual organs (archegonia and antheridia) on the under surface. When ripe the archegonia extrude an attractive substance towards which the male elements from the antheridia swim. One male element (spermatozoid) enters each archegonium and fuses with the egg within. The resultant embryo develops a root and leaves and assumes the familiar fernlike appearance.

From the gardener's point of view hardy ferns are valuable to fill moist, shady places for which the choice of flowering plants is limited, but the use of exotic ferns, except as specimens, or in elaborate winter gardens, has fallen into disuse, since some consider that space can be employed to greater advantage by flowering plants. This is purely a matter of taste; the beauty of the fern is lasting, that of the flower ephemeral.

#### Suitable Soil and Situation

Hardy ferns are not particular as to soil, though to obtain the best results a mixture which contains a considerable percentage of decayed leaf-mould or peat is desirable, or, failing this, some old stable manure should be mixed with the loam when making up the bed. The situation is more important; the north side of a wall or hedge, where less hardy things are difficult to grow, will suit ferns admirably. It is well not to plant them too near ivy, however, as this climber is so greedy a feeder that it speedily takes all the nourishment away from the ferns, especially if they are of choice kinds. The ordinary brake fern, or bracken, will grow anywhere, but except for very smoky and shady town gardens, its employment in

any quantity is not recommended as it is a greedy feeder.

Exotic ferns should be taken in hand in early spring, when the new growth starts. They will thrive in any ordinary potting mixture, one which contains a liberal admixture of silver sand for preference, and they may be shifted into larger pots when necessary, at any time of the year except winter. Ferns are most easily increased from spores, which are found upon the undersides of the leaves. When these are ripe the most fruitful leaf or leaves should be severed from the parent fern, and stored away in a box or piece of paper for a few days, and kept dry until the spore cases burst. The spores should then be lightly sown upon the surface of a box of finely sifted potting soil, and kept moist. Tiny ferns will appear, developing from prothallia, and these should be very carefully potted into thumb-pots when large enough to handle, and afterwards repotted as desired.

#### Maidenhair and Ribbon Ferns

When ferns such as the maidenhair, ribbon-fern, or any of the native species have been grown in the greenhouse, it will be found that the top-soil of the pots is already sown with their spores. If this is removed to a shallow pan and covered with glass, it will soon be covered with prothallia. Observation of the evolution of the adult fern from this beginning is a valuable lesson in botany.

Gold and silver ferns are popular names given to several species to denote their appearance. It is due to the under surface of the leaves being coated with fine particles of white or yellow wax, which looks silvery or golden. *Cheilanthes argentea*, an Asiatic species, is an example of a silver fern. Others of the same genus are *C. clevelandi* (N. America), *C. lanosa* (Western U.S.A.), and *C. myriophylla* (tropics). The genus *Ceropteris* also affords examples of

silver ferns in *C. chrysophylla* (tropics), *C. decomposita* (S. America), and *C. sulphurea* (W. Indies).

**Bibliography.** Structure and Development of Mosses and Ferns, D. H. Campbell, 1895; Wayside and Woodland Ferns, with Figures of British Species, E. Step, 1908.

**Fernandez, JUAN** (c. 1536-1602). Spanish navigator. A native of Cartagena, Fernandez spent his life as a pilot on the Pacific coast. In 1571 he discovered the island now called by his name, on which he vainly tried to settle some Indians. His skill as a sailor won him the nickname of the wizard, and also brought him to the notice of the Inquisition. See Juan Fernandez.

**Fernando de Noronha.** Island in the Atlantic, belonging to Brazil. It is about 200 m. E.N.E. of Cape St. Roque, 8 m. long by 1½ m. wide, is of volcanic origin, reaching an elevation of 1,100 ft., and has several good harbours protected by forts. The surface is rugged, but fertile, producing cereals, cotton, and fruit. At Remedios is a convict settlement, with a cable and wireless telegraph station. The island was discovered by a Portuguese navigator, whose name it bears. It is a landing point for aeroplanes between Europe and S. America. Pop. 1,200.

**Fernando Po.** Island in the Bight of Biafra, belonging to Spain. The key to this portion of the African coast, it is mountainous and fertile. Of volcanic origin, it is 35 m. long and 22 m. broad. Densely forested and covered with luxuriant vegetation, it yields sugar-cane, bananas, and yams, while cotton, coffee, rice, tobacco, and cinchona are cultivated. The highest mt., Clarence Peak, is 10,190 ft. The island is inhabited by a Bantu tribe, the Bubis, and a few negroes.

Santa Isabel, the chief town, is the administrative capital of the Spanish possessions in the Bight of

Biafra. Rubber and palm oil are exported. The climate is unhealthy. The island is named after Fernão do Po, its Portuguese discoverer in 1471. It was ceded to Spain in 1778. Area about 800 sq. m. Pop. 26,405.

**Ferney** or **FERNÉY-VOLTAIRE.** Village of France, in the dept. of

Ferney. The château built by Voltaire in 1758, which was his home for twenty years

1. Royal fern, *Osmunda regalis*. 2. Hart's-tongue, *Scolopendrium vulgare*. 3. Sea spleenwort, *Asplenium marinum*. 4. Hard fern, *Blechnum spicant*. 5. Maidenhair spleenwort, *Asplenium trichomanes*. 6. Common polypody, *Polypodium vulgare*. 7. Lady fern, *Athyrium filix-foemina*. 8. Male fern, *Dryopteris filix-mas*. 9. Prickly shield fern, *Athyrium aculeatum*

**FERN: SPECIES FOUND IN THE BRITISH COUNTRYSIDE**

Ain. It stands near the Swiss frontier, 4 m. N.W. of Geneva. The château de Ferney was built by Voltaire, who lived in it from 1758 to 1778; it contains numerous memorials and personal relics of the philosopher, who in 1768 founded a watch factory, which at one time employed 800 hands. In the town hall is a statue to Voltaire (*q.v.*), and his name was officially added to that of the town in 1878.

**Fernie.** City of Canada, in extreme S.E. of British Columbia. It lies 650 m. E. of Vancouver on the C.P.R., is on the Elk river, and is a tourist centre for the Kootenays. Coal mining is carried on, and the city owns its light, power, and water systems. Pop. 2,513.

**Fern Owl.** This bird is more commonly called the nightjar (*q.v.*).

**Fern Palm** (*Cycas revoluta*). Tree-like perennial of the family Cycadaceae. A native of China, it has a stout stem, in old individuals as much as 7 ft. high, crowned by the arching, palm-like leaves. These are cut into narrow segments in a feather-like manner, and vary in length from 2 ft. to 6 ft. The reproductive organs are found in the heart of the leaf-crown: the males in cones, whose scales bear anthers on their under surface; the females bearing ovules in the marginal notches of woolly, leaf-like organs.

**Ferns.** Town of Eire, in co. Wexford. It stands on the Bann, 74 m. S. of Dublin by rly. Its interest is wholly historical. It is the seat of R.C. and Protestant bishops. Buildings of interest are the two cathedrals, the episcopal palace, ruins of a Norman castle, of a church, and a monastery. The town grew up around a monastery founded by S. Edan about 600. The kings of Leinster had a palace here. The Protestant diocese was united with Ossory in 1836. James I made Ferns a chartered town, and until 1800 it sent two members to the Irish parliament. Pop. 1,576.

**Ferozepore.** District and town of W. Punjab, Pakistan. The area of the district is 4,085 sq. m. There are no important manufactures; the chief crops are wheat, grain, barley, and millet. Half the cultivated area is irrigated. Ferozepore town, founded in the 14th century, is situated at the junction of the Rajputana and North-Western rlys., some 4 m. from the Sutlej. It is the centre of a considerable grain trade. Battlefields of the Sikh War, 1845-46, lie to the E. Pop. of dist., 1,423,076. Hindus, Sikhs, Muslims; town, 72,000.

**Ferozeshah,** BATTLE OF. British victory in the first Sikh War. On Dec. 21, 1845, Sir Hugh Gough, who had just won the victory of Moodka, advanced against the Sikhs, and after a violent cannonade attacked with his infantry. The first British attack was repulsed with heavy loss. In the second effort the Sikhs were routed, losing 73 guns. See Sikh Wars.

**Ferragus,** FERRACUTE, FERRAUTE, OR VERNAGU. Giant of early French romances. In the Charlemagne legends he overcomes all that monarch's paladins except Roland, by whom he is slain. In Ariosto's Orlando Furioso he is a Saracen who throws away his helmet, declaring that he will never wear another until he has won that of Orlando, by whom he is killed.

**Ferranti,** SEBASTIAN ZIANI DE (1864-1930). An English scientist, born at Liverpool, April 9, 1864. He devoted his life to the improvement of existing methods of supplying and measuring electrical power. In 1882 he patented the Ferranti alternator, and then invented the electrical meter bearing his name. The Ferranti meter consists of an electro-magnet containing a thin disk of mercury, and the rotation of the disk serves as a measure of the strength of the current passing through the meter (see Meter, Electrical). In 1886 he set up his own generating station in Liverpool, and in 1892 founded the Ferranti electrical engineering works at Hollinwood, Lancs. He was president of the Institute of Electrical Engineers, 1910-11, and was elected F.R.S. in 1927. He died Jan. 13, 1930.

**Ferrar,** NICHOLAS (1592-1637). English theologian and founder of the Little Gidding community. Son of a London merchant, he was educated at Clare Hall, Cambridge, and worked for the Virginia Company, 1619-23. He was elected to parliament, but in 1625 retired, with his mother and brother-in-law, Collet, and their families, to the manor of Little Gidding, Hunts, to a secluded life of devotion, study, and good works. In 1626 he was ordained deacon by Laud. He died Dec. 4, 1637.

The members of Little Gidding household were famed for their skill in embroidery, bookbinding,

and "scrap book" making, and examples survive in the British Museum and elsewhere of cunningly constructed "harmonies," or "concordances" of the Bible, illustrated with prints collected by Ferrar on his travels. The "Arminian Nunnery" was twice visited by Charles I, and was broken up by the Puritans in 1647; it figures in J. H. Shorthouse's John Inglesant, and in Izaak Walton's Life of George Herbert.

**Ferrar,** ROBERT (1500-55). English martyr. He studied at Oxford and later was head of a religious house in Yorkshire, but became prominent on the accession of Edward VI. Owing to the influence of Somerset he was made bishop of St. Davids. He was a zealous reformer, but charges were brought against him, and Somerset having fallen from power, he was imprisoned in 1552. In 1554 his bishopric was taken from him, and he was put on his trial. Found guilty, he was burned at Carmarthen, March 30, 1555. The chief charge against him was that he had violated his vow of chastity by marrying.

**Ferrara.** Prov. of N.E. Italy. It is bounded N. by the river Po and E. by the Adriatic Sea. Area,

Ferrara. Façade of the cathedral of St. George, the lower part dating from 1135

1,019 sq. m. Low-lying and marshy in parts, it lies mostly within the delta formed by the Po and its branches and by the Primaro and the Panaro, and embraces the lagoons of Comacchio (*q.v.*). It was the scene of bitter fighting in April, 1945. Fairly fertile, it produces rice, grain, wine, hemp, silk, salt, and fish. The capital is Ferrara. Pop. 366,371.

**Ferrara.** City of Italy, capital of the prov. of Ferrara. It stands about 3 m. S. of the river Po di Volano, 30 m. by rly. N.N.E. of Bologna. An archiepiscopal see, its cathedral dates from the early 12th century. The city is

surrounded by crumbling walls, but its palaces and other structures attest its former splendour. Several churches and palaces were damaged during the Second Great War. Ferrara was the seat of the court of the family of Este (*q.v.*), and their castle (now utilised as public offices) was a moated fortress with four towers. The university was founded in 1264, and its library is rich in MSS. of Tasso, etc. Among other buildings are a picture gallery, and the houses of Ariosto and Guarini.

From the 14th to the 17th century Ferrara was a prosperous city, and in the 15th was noted for its school of painting. It has normally a trade in hemp, soap, wax, candles, glass, and silk. Guarini and Savonarola were natives. It came into the possession of the Este family in 1146, and was their capital until 1598, when it passed to the papacy. In the papal interest its fortress was garrisoned by the Austrians during the revolutionary times of 1832-59, after which the city joined the kingdom of Italy. In the Second Great War the British 8th army captured Ferrara from the Germans, April 24, 1945. Pop. 119,265.

**Ferrara, ANDREA.** Italian sword-maker of the 16th century. He was working in Belluno in 1585, and swords bearing his name were used in Scotland in the 16th and 17th centuries. The steel was tempered by a process claimed to be that invented by the swordsmiths of Damascus. The name Andrea Ferrara was afterwards employed rather as a trademark than as implying any connexion with the original maker.

**Ferrara-Florence, COUNCIL OF.** The oecumenical council of the Church held at Ferrara, and later at Florence, between April, 1438, and July, 1439. It was called by Pope Eugenius IV as a continuation of the council of Basel, and had as its main object the healing of the breach between the Roman and Greek churches. The Latin emperor, John Palaeologus, representing the Greeks, brought a large delegation at the pope's invitation to Ferrara. The scene of the council was changed to Florence in January, 1439. The debates turned chiefly on the Filioque controversy, *i.e.* the question whether the Holy Ghost proceeds from the Father and Son (*ex Patre Filioque*), or from the Father alone. On July 6 a decree was published which declared that, while the pope was the supreme head of all the Church,

the rights of the Eastern patriarchs were to be unaffected.

The two churches were thus momentarily united in intention, but not in effect. Isidore of Kiev was sent as legate to Constantinople by Pope Nicholas V in 1452, in order to push the process of union forward, but before he had accomplished his mission the city was taken by the Turks, 1453. This undid the work of the council, the last effort at Eastern and Western reunion.

**Ferreira, ANTONIO** (1528-69). Portuguese poet. Born in Lisbon, he was educated at Coimbra university. Famous as one of the earliest and the most distinguished of those who introduced the classical mode into Portuguese literature, he used the Italian decasyllable in his sonnets, substituting a measured austerity for the formless verse of his predecessors. His great work, the *Castro*, was the first verse tragedy written in Portuguese, and one of the earliest in modern European literature. He died Nov. 29, 1569.

**Ferrel, WILLIAM** (1817-91). American meteorologist. Born in Bedford co., Pa., he early turned his attention to meteorology, then a neglected science, and his researches soon won him world-wide fame. In 1867 he became a member of the U.S. coast and geodetic survey, and began to formulate the laws of meteorology on a scientific basis. His invention of a tide-predicting machine came into general use in the U.S. government coast surveys. He wrote *Tidal Researches*, 1874; *Meteorological Researches*, 1877-82; and *Popular Treatise on the Winds*, 2nd ed. 1898.

**Ferrel's Law.** Law of the deflection of bodies moving in the air of the rotating globe. If a body moves in any direction except E. or W. on the earth's surface the rotation of the earth will cause it to be deflected to the right of the direction of movement in the N. hemisphere, and to the left in the S. hemisphere. The law is an example of the general case in mechanics when a body acted upon by two forces moves in a direction compounded of the original directions of the forces. In the N. hemisphere a body forced northwards receives an eastward impulse from the earth's rotation, and moves towards the N.E.

**Ferrer, FRANCISCO** (1859-1909). Spanish revolutionary. Born near Barcelona, he was a railwayman,

1877-85, and studied socialism and rationalism. He was closely associated with the republican agitator Zorrilla, with whom he lived in Paris. Ferrer returned to Barcelona in 1901, and was prominent in founding lay schools and centres of advanced socialist and rationalist teaching. In 1907 he was acquitted of having taken part in the attempt to assassinate the king in 1906. In July, 1909, he was active in the insurrections in Barcelona, aiming at the establishment of a new anti-Catholic state in Catalonia. Condemned as the prime instigator, he was shot on Oct. 13, his execution raising much indignation, mainly against Roman Catholic influence in Spanish politics.

**Ferrero, GUGLIELMO** (1871-1942). An Italian historian and sociologist. Born at Portici, near Naples, July 21, 1871, he made his reputation as a historian with *L'Europa Giovane*, 1897. Professor of history at Rome, he moved to Geneva in 1930, and held the chair of modern history at the university there. A profound thinker, he was chiefly concerned in his later works with diagnosing the crisis in western civilization. His most important works included *History of the Roman Republic*, published 1902-09, and translated into almost every European language; *Tra i Due Mondi*, 1913; *Adventure*, 1936; *Reconstruction*, 1940; *Pouvoir: Les Génies Invisibles de la Cité*, 1942. He died Aug. 3, 1942.

**Ferrers, EARL.** British title borne since 1711 by the family of Shirley. The family of Ferrers first appeared in England with William the Conqueror. Henry Ferrers was a great landholder, especially in the North Midland counties, and his son Robert was made earl of Derby in 1138. His successors, who had Tutbury Castle for their main stronghold, were known as earls Ferrers or earls of Derby. John, son of the 6th earl, was summoned to parliament in 1299 as Baron Ferrers of Chastley. This title passed to the family of Devereux in 1461 and remained therein until 1646, when it fell into abeyance.

The Shirleys became connected with the title through the marriage of Sir Henry Shirley with the daughter of Robert Devereux, 2nd earl of Essex. In 1677 Sir Robert, a descendant of Sir Henry, was allowed to assume the baronial title, and in 1711 he was made Viscount Tamworth and Earl Ferrers. Laurence, the 4th

earl (1720–60), was the last peer in England to be executed as a felon. In 1745 he succeeded to the title on the death of his uncle. In a moment of anger he shot his steward, Johnson, and was tried for murder by his peers in Westminster Hall. Found guilty, he was hanged at Tyburn, May 5, 1760. Robert, the 12th earl, was born in 1894 and succeeded his father in 1937. Tamworth Castle, long the family seat, no longer belongs to the Shirleys.

**Ferrers, GEORGE** (c. 1500–79). English politician and poet. He was page of the chamber to Henry VIII, who took him with him in the Scottish and French wars and bequeathed him 100 marks. He is mainly remarkable for having produced and probably written masques for Edward VI's Christmas entertainments in 1551–52 and for having contributed several tragical episodes to Baldwin's *Mirror for Magistrates*, 1559–78.

**Ferret** (*Putorius*). Domesticated variety of the polecat, kept for hunting rabbits. According to Roman writers the polecat came from Africa, and although it is now quite unknown there, it is probable that it was originally domesticated in N. Africa or Spain, and afterwards introduced into Italy. As a result of domestication, the polecat became smaller and slimmer, and albinos became the rule instead of the exception. In this way the ferret developed. It is a somewhat delicate animal, and its intolerance of cold suggests its Mediterranean origin. It breeds readily with the wild polecat, and the brownish variety known as the polecat-ferret is probably the result of such crosses. The ferret is only semi-domesticated. It has no affection for its owner, is very ferocious, and is as likely to bite the hand that feeds it as any other. It therefore needs to be handled with caution, the best way being to grasp it close behind the shoulders.

The method of hunting a rabbit warren with ferrets is to net or stop all the holes except one, at which the ferret is inserted. The rabbits, finding an inveterate enemy on their track, bolt for the holes and are thus caught in the nets. It is a common practice to muzzle the ferret; otherwise, if it catches a rabbit in the burrow, it will remain there to make a meal of it.

Ferrets need great care to keep them in good health, warmth and scrupulous cleanliness being the chief essentials. Plenty of warm litter must be provided, and the hutch should be thoroughly cleaned and disinfected at least once a week. The food should consist of fresh bread and milk, and a little raw meat may be given once a week. Ferrets breed freely in captivity and usually rear two families in the year. See Rabbit.

**Ferrex and Porrex.** One of the titles under which the earliest extant English tragedy is known. See Gorboduc.

**Ferric Salts.** Iron forms, with acids, two series of salts, ferrous and ferric. The ferric salts are generally yellowish or reddish brown in colour, and are reduced to the ferrous state by means of zinc. Ferric chloride ( $\text{FeCl}_3$ ) is prepared in the anhydrous state by heating iron wire in a current of dry chlorine gas, and in the form of solution by dissolving iron wire in hydrochloric acid and then passing chlorine into the liquid until it smells of the gas.

As a tincture ("steel drops") ferric chloride is used in medicine as a tonic. With a soluble thio-cyanate, ferric chloride gives an intense blood-red colour. Ferric sulphate,  $\text{Fe}_2(\text{SO}_4)_3$ , ob-

tained by oxidising ferrous sulphate by means of nitric acid, is used in combination with logwood to dye cotton black. Iron alum is a compound of ferric sulphate and potassium sulphate. This and ferric nitrate are used in dyeing. Ferric oxide, which occurs naturally and is also produced by distilling ferrous sulphate, is known as red ochre and colcothar, and used as colouring matter and polishing material.

**Ferricyanides.** Salts of ferricyanhydric acid,  $\text{H}_3\text{Fe}(\text{CN})_6$ , first made by Gmelin by decomposing lead ferricyanide with dilute sulphuric acid and evaporating the solution after filtration. Potassium ferricyanide or red prussiate of potash is prepared by passing chlorine through a solution of potassium ferrocyanide or over the dry salt until it no longer gives a blue colour with a ferric salt.

The salt is in deep red crystals and forms with water a dark yellow solution which darkens with age and becomes converted into ferrocyanide. On adding ferrous sul-

phate (green vitriol) to potassium ferricyanide solution a blue precipitate known as Turnbull's blue is obtained. When chlorine is passed into a solution of potassium ferricyanide a green precipitate known as Prussian green is formed, the appearance of which is the indication that the end of the process has been reached. Potassium ferricyanide, a powerful oxidising agent, when employed with caustic potash, is used in the preparation of ferro-prussiate paper upon which "blue prints" are made. See Colour Printing.

**Ferrier, JAMES FREDERICK** (1808–64). Scottish metaphysician. Born at Edinburgh, June 16, 1808, he was professor of moral philosophy and political economy at St. Andrews from 1845 until his death, June 11, 1864. Like Berkeley, he is an idealist and immaterialist. There is no such thing, he believes, as independent matter; all external things exist only subjectively; the only material world which really exists is one with which intelligence co-exists. The conscious subject is inseparably connected with the conceived object. At the same time, he does not deny the existence of the real material world *per se*, as distinct from that known to us through the subjective medium of space and time, but declares it to be simply unknowable. His most important work is *Institutes of Metaphysics*, 1854.

**Ferrier, PAUL** (1843–1920). French dramatist. Born at Montpellier, he studied for the bar, but turned to playwriting after the production of his first piece, a verse play, *La Revanche d'Iris*, in 1868. He wrote and collaborated in a large number of opera libretti, comic operas, and comedies, well known in France for their gaiety and humour. Among the most successful were *Les Mousquetaires au Couvent*, 1880; *Tabarin*, 1884; *L'Article 231*, 1891; *La Belle Mère*, 1898. He died Sept. 11, 1920. *Prom. Ferry-ay.*

**Ferrier, SUSAN EDMONSTONE** (1782–1854). Scottish novelist. Born at Edinburgh, Sept. 7, 1782, she published her first novel, *Marriage*, in 1818, followed by *The Inheritance*, 1824, and *Destiny*, 1831. Published anonymously they gave a shrewdly satirical

Ferret. The domesticated polecat which is used for rabbiting

picture of contemporary Scottish society, and won great popularity and the praise of critics as eminent as James Hogg and Scott. She was known familiarly as Scott's "sister-shadow," and died at Edinburgh, Nov. 5, 1854. Her *Recollections of Visits to Ashestiel and Abbotsford* were published in 1881.

**Ferrite.** In metallurgy, the form of iron which is stable at temperatures below 900° C. Above this temperature iron containing only small amounts of carbon is in the form of a solid solution of carbon in gamma-iron. This is called austenite and has a face-centred cubic crystal lattice. At 900° C. it transforms to alpha-iron or ferrite, which has a body-centred cubic lattice and will hardly dissolve any carbon at all. The excess carbon dissolves in the remaining gamma-iron and a typical eutectoid (*q.v.*) is formed, known as pearlite. Ferrite is feebly magnetic above 780° C., but below this point strongly so. By itself ferrite is not very strong and steels owe their hardness and strength largely to the carbide, cementite.

**Ferro-Alloys.** Series of alloys of iron with high proportions of manganese, chromium, vanadium, silicon, molybdenum, tungsten, or similar element. They are widely used in steel making, being the most convenient form in which to add the various alloys used for deoxidising and alloying. With between 10 and 90 p.c. of the alloying element, they have a hard brittle character. Ferro-manganese is still made in the blast furnace much as pig iron is. Ferro-silicon and ferro-chrome are made more cheaply and with lower carbon content in the electric arc furnace. For ferro-silicon the furnace is fully charged with iron ore or scrap iron and quartzite and melted gradually away from the electrodes by the great local heat generated by the arc. The use of the electric furnace has contributed to the development of alloy steels.

**Ferro-Concrete.** Material used in building. It is described under Concrete. *See also* Building.

**Ferrocyanides.** Salts of ferrocyanic acid,  $H_4Fe(CN)_6$ . Most ferrocyanides are coloured, and those of the soluble alkalis are non-poisonous, although from them hydrocyanic or prussic acid can be readily prepared. The most important of these salts is potassium ferrocyanide or yellow prussiate of potash. The old process of manufacture consisted in fusing together potassium carbonate with iron borings and

nitrogenous animal matter such as leather cuttings or woollen rags, and lixiviating the mass with water. Potassium ferrocyanide is a by-product of the manufacture of coal-gas. It is used in producing Prussian blue (ferric ferrocyanide) and other cyanogen compounds in calico-printing, and for case-hardening iron.

**Ferrol.** Seaport of Spain, in the prov. of Corunna. It stands on the N. arm of the Bay of Betanzos, and is the chief Spanish naval station on the Atlantic. The harbour is sheltered and commodious, with shipbuilding yards, docks, and quays, defended by both nature and art. It has a first-class arsenal, a naval academy, and many fine public buildings. It manufactures naval stores, leather, sailcloth, cotton and linen, and exports pit-props, vinegar, brandy, and sardines. The British besieged it in 1799, and took it in 1805, after defeating the French fleet off the bay. It was captured by the French after six weeks' blockade in 1823. Pop. 63,714.

**Ferrous Salts.** Group of iron salts. Ferrous sulphate,  $FeSO_4 \cdot 7H_2O$ , green vitriol, or copperas, is obtained in large quantities by exposing the pyrites occurring in coal-measures to the atmosphere. The soluble ferrous sulphate together with the excess of sulphuric acid, runs into underground tanks where the excess of acid is removed by means of scrap iron. The liquid, on evaporation, yields crystals of ferrous sulphate.

Ferrous sulphate is used in the manufacture of ink, in dyeing and tanning, and in the preparation of Prussian blue. The pure salt is used in medicine. Ferrous oxide,  $FeO$ , has the property, when freshly made, of oxidising with incandescence on exposure to the air. Ferrous iodide,  $FeI_2$ , is used in medicine, as are also ferrous phosphate,  $Fe_3(PO_4)_2 \cdot 8H_2O$ , and ferrous carbonate,  $FeCO_3$ . The last-named is contained in chalybeate waters, from which the ferrous carbonate is deposited, on exposure to air as the hydrated oxide.

**Ferrule.** A short metal tube driven tightly into a hole in an iron or steel pipe and soldered or otherwise secured to another pipe so as to connect the two. It is also a short tapered tube driven into the end of a boiler-tube where it passes through the fire-box plate. The wedging action of the ferrule expands the boiler-tube end and ensures a tight connexion between the boiler-tube and the plate. There are also other types of boiler-tube ferrules. In common speech the word is used of a metal ring on the handle of a tool, and of the thimble-shaped covering at the end of a walking-stick or umbrella to protect it against wear.

**Ferry.** A public passage-way across water, usually linking up roadways or tracks on both banks. The most usual means of transport is a floating vessel of some kind which, for small loads and short distances, is frequently a flat-bottomed boat, guided by a taut wire cable and propelled by an endless rope. For heavy loads the ferry-boat may be moved to and fro by a windlass on board, which picks up and pays out a chain crossing the bed of the river. Where there is a strong current in one direction only, the ferry-boat may be attached to a chain the other end of which is moored in midstream some distance higher up, the current being used to move the boat across by oblique pressure. *See* Congo illus.; Train Ferry.

In the Second Great War, the term was also applied to the delivery of aircraft to the depots and first-line units. Ferry Command (*q.v.*) of the R.A.F. was formed for trans-Atlantic operations, and, within Great Britain, Air Trans-

Ferry. The chain ferry which crosses the Tamar from Cornwall to S. Budeaux, nr. Plymouth, Devon

port Auxiliary (*q.v.*) carried out a similar function.

**Ferry, Jules François Camille** (1832-93). A French statesman. Born at St. Dié in the Vosges, April

Jules Ferry,  
French statesman

15, 1832, he became a lawyer and a journalist. In 1869 he was chosen as deputy for Paris, being already known as a vigorous opponent of the emperor. When Paris was besieged, as prefect of the Seine he was responsible for its government. After being minister at Athens, he returned to the chamber of deputies in 1873 and entered the ministry in 1879. In 1880 he became premier for a short term, and was again premier, 1883-85, being in the meantime minister for education. In 1885 he retired, but was active in politics until his murder by a lunatic, March 17, 1893, just after he had been chosen president of the senate. Ferry did much to promote secular education, and to establish French influence in Africa and Indo-China.

**Ferrybridge.** Town of the West Riding of Yorkshire, England. It stands on the Aire, 2 m. N.E. of Pontefract, and has a railway station. In 1461 it was the scene of an engagement during the Wars of the Roses. Here is a large electric power station, close to the Great North Road.

**Ferry Command.** Organization founded by 85 (transport) group of the R.A.F. for ferrying American-built aircraft to Great Britain during the Second Great War. Early in the war the ferrying of military aircraft across the Atlantic was the responsibility of the ministry of Aircraft Production, but in July, 1941, the work was transferred to the newly-formed Ferry Command. A large proportion of the pilots of Ferry Command were recruited from Imperial Airways, and the whole organization was under the command of Air Chief Marshal Sir Frederick Bowhill. In May, 1943, Ferry Command was absorbed by the R.A.F. Transport Command. See Atlantic Ferry.

**Fersen, Fredrik Axel, Count von** (1719-94). Swedish soldier and politician. Of Scottish descent, Fersen was born at Stockholm, and as a young man served with the French army with distinction. In 1748, he fought against Prussia in the Seven Years' War. Marshal of

the Swedish diet in 1755, and again in 1769, Fersen was prominent as leader of the aristocratic party (the "Hats"). From 1786 he was an open and powerful opponent of Gustavus III, and was put under arrest for a time in 1789, after which he retired.

**Fersen, Hans Axel, Count von** (1755-1810). Swedish soldier. Born at Stockholm, Sept. 4, 1755, he served in the Swedish army. Afterwards he resided at the court of Louis XVI of France, with whom he became a great favourite. During the American War of Independence he fought under Lafayette. When the king and Marie Antoinette, to whom Fersen was devoted, fled to Varennes in 1791, Fersen was the driver of the coach. After his return to Sweden he was murdered by a mob, June 20, 1810, on suspicion of having been concerned in the death of the Crown Prince. His innocence was later proved.

Hans von Fersen,  
Swedish soldier

**Fertilisation.** Biological term for the union of two dissimilar cells which precedes the production of a new individual by sexual means. Many plants and animals produce two kinds of monoploid reproductive cells or gametes, a smaller and often motile male, and a larger usually non-motile female. Neither can normally continue existence independently, and union of such cells periodically is usually essential for the maintenance of the race. Occasionally new individuals may arise from female structures which have not been fertilised: this constitutes parthenogenesis.

In some species both male and female reproductive organs are present in the same individual. When dissimilar gametes formed by one organism unite, the process is termed self-fertilisation. In higher animals cross-fertilisation is the rule, and in this process the sperm and the ovum which unite come from two distinct members of opposite sex. Fertilisation is facilitated by the movement of the male gamete. Typical sperms of animals consist of a mainly nuclear head and a propelling tail, which correspond with the body and cilia of the antherozooids of those plants whose male gametes swim to the female to effect zoidiogamous (*Gr. zoidios, of animals*) fertilisation. The male gametes of

other plants have no obvious means of propulsion, but some reach the oosphere by means of fertilisation tubes; the process is then siphonogamous fertilisation.

The female gamete is undoubtedly co-active in bringing about fertilisation: in many, probably all, instances it exudes soluble material to guide the male cell in chemotaxis (*q.v.*); the oospheres (*q.v.*) of a number of lower plants provide a special receptive region through which the male cell enters, and a number of animal ova appear to engulf the male cell when the latter has made contact and active movement has ceased. Female gametes generally also inhibit the entry of more than one male cell by forming membranes around themselves after the first has penetrated. The nuclear portion of the male gamete sometimes, though not indisputably always, accompanied by cytoplasmic structures sinks into the female cell where ultimately all trace of any male cytoplasm is lost and the male nucleus coalesces with the female nucleus. Fertilisation is then complete, and the single diploid cell so formed is a zygote, the first cell of a new organism.

The process of fertilisation has a twofold effect: it initiates the physiological activity which results in development of the zygote; it is complementary to meiosis in the reorganization of nuclear material with the accompanying reassortment of Mendelian characters. Uncertainty of the fate of parts of male gametes other than the nucleus leaves doubt as to whether male parents transmit any characters other than those borne by the nucleus. Since, however, the female gamete habitually has a considerable bulk of material outside its nucleus and this becomes part of the zygote, there is a considerable possibility that female parents may pass on to their offspring characters additional to those carried by the chromosomes. See Cytology; Embryology.

**Fertiliser.** Substance applied to the soil to furnish plant foods. The term manure is used for organic substances which confer benefits on the soil in addition to providing a plant food. In general, fertilisers contribute one of the essential plant foods, nitrogen, phosphates, or potash, but a few give two or three together. They are described according to the essential plant food they supply, and in relation to the rate at which the particular substance is made available to the plant. Thus,

there are nitrogenous, phosphatic, and potassic fertilisers of quick and of slow acting propensities.

Nitrogen influences the development of stem, leaves, and root and thus the size of the plant; phosphate has an effect on the root; potash is concerned with carbon assimilation and hence with fruit and seed formation. In the absence of potash plants are more liable to fungoid diseases. The optimum effect of any one fertilising constituent cannot be obtained except in the presence of an abundant supply of the other two; hence, unless there is sufficiency of the others, the use of one alone is not recommended.

Of the nitrogenous fertilisers, sulphate of ammonia, nitrate of soda, nitrate of lime, and calcium cyanamide represent the quickly acting form, all possessing a high percentage of nitrogen; calcium cyanamide also has a high percentage of lime. Bones long formed the basis of supplies of phosphate, but now the supply is augmented by quantities of rock phosphate. Raw bones contain about 10 p.c. of fat; when this is removed the resulting product ground is a valuable fertiliser.

#### Composition of Superphosphate

Superphosphate is water-soluble and obtained by treating bones and rock phosphate with sulphuric acid. Basic slag, a by-product in the manufacture of steel, is another source of phosphate; the latter is insoluble in water but soluble in dilute acids such as exist in most soils. Basic slag also contains lime.

Potash comes from the ash of plants after incineration, the largest supplies from the Stassfurt deposits in Germany, from Alsace, and from Palestine. Potash from these sources exists as chlorides and sulphates in combination with chlorides and sulphates of magnesium and sodium. The amount ranges from about 48 p.c. in sulphate of potash to 12 p.c. in kainit. In Great Britain potash is applied to potatoes, sugar beet, mangolds, and market garden crops, and, on light land, to clovers, permanent grass, and, as far as possible, cereals.

Farmyard manure is by far the most general and valuable of all organic manures; its chemical composition is variable, but an average figure of fertilising constituents is nitrogen 10-15 lb., phosphoric acid 4-9 lb., potash 9-18 lb. Apart from its actual fertilising influence, farmyard manure has a most salutary effect on the physical condition of a soil

by increasing its workability and moisture-retaining capacity, in addition to contributing essential bacteria.

**Ferule** (Lat., *ferula*, fennel, cane, *ferire*, to strike). Instrument of punishment. The stalk of the giant fennel, *Ferula communis*, was used as a rod or cane, to which it gave its name. The word is applied also to a sole-shaped strap, comparable to the Scottish tawse, with which boys are beaten on the palms of the hands in some schools.

**Fescennine Verses.** Improvisations in dialogue form made at rustic gatherings in ancient Italy, the origin probably of the native Roman *satura*, or satire, in which the speakers made capital out of the faults and follies of their neighbours. As a feature of wedding celebrations they were commonly characterised by broad licentiousness. Hence the derivation of the name from the Lat. *fascinum*, a phallic emblem, by some etymologists who deprecate its other derivation from Fescennia on the ground that the custom was widespread throughout Italy, and not peculiar to that small Etruscan town. From the Fescennine verses the epithalamium, or nuptial song, was ultimately developed, a literary form of which Catullus, for one, made exquisite use, and which has been successfully reproduced in the literature of many countries, notably by Herrick in England.

**Fesch**, JOSEPH (1763-1839). French cardinal. Born at Ajaccio, Jan. 3, 1763, the step-brother of Letizia Bonaparte, he was archdeacon of Ajaccio until the French revolution, when he retired. He had always befriended the Bonaparte family, and in 1802 Napoleon made him archbishop of Lyons, and procured for him a cardinal's hat. Ambassador at Rome in 1804, he persuaded Pius VII to crown Napoleon in Paris, and was made grand almoner and senator of the Empire. His position as intermediary between Napoleon and Pius was extremely difficult during 1806-07, and Fesch's relations with both became strained, especially after the Gallican council of 1811, from the presidency of which the emperor dismissed his uncle. Retiring to Rome on the fall of the Empire in 1814, he died there May 13, 1839.

**Fescollising.** Method of improving the resistance to corrosion or wear of a steel article by depositing electrolytically another metal on the surface. Nickel and chromium are commonly used; they may be deposited only on

the parts submitted to most wear by protecting the other parts from the electrolyte with a layer of grease, etc. See Electrolysis.

#### Fescue Grass

(*Festuca*). Extensive genus of grass. Of the family Gramineae, they are natives of cold and temperate regions. The flattened flower spikelets are grouped in panicles or racemes; there being three or more flowers in each spikelet. Many species are among the most valuable of meadow and pasture grasses, being rich in saccharine matter. Sheep's fescue (*F. ovina*), with bristle-like leaves, which grows in hilly pastures that are dry and open; meadow fescue (*F. pratensis*), and hard fescue (*F. duriuscula*) are most useful for this purpose.

**Fess** (Lat. *fascia*, band). In heraldry, a horizontal band carried across the middle of the shield

Fess, in heraldry

and occupying one-third of the field. It is one of the ordinaries (q.v.). The middle of the field is known as the fess point. A shield or charge divided by a horizontal line in the middle is said to be "per fess"; but if it is divided into any number of horizontal bands above four, it is called "barry." If there are three divisions it is "tierced" or "tiercy per fess"; if four, "quartered per fess." Charges placed in horizontal rows are termed "in fess."

**Festiniog** or **FESTINIOG**. Urban district and town of Merionethshire, Wales. It is 16 m. N. of Dolgelly, and stands amid the hills, surrounded by beautiful scenery, one feature of which is the Cynfael Falls. The town, not to be confused with Blaenau Festiniog, is

Meadow Fescue, *Festuca pratensis*

served by railway. The main industry is the large slate quarries, which employ most of the male inhabitants. Pop. 9,072.

**Festival** (Lat. *festivus*, joyful). Days on which some deity or person was honoured or the memory of some important event kept with certain solemnities, ordinary work being as a rule suspended. Such festivals or feasts no doubt were originally nature festivals, connected with its changing phenomena, its decay in winter and renaissance in spring (see Adonis). They were partly merry makings and thanksgivings for benefits received, partly prayers for benefits to come, and partly ceremonies to appease the anger of the gods for sins committed, though even from the latter the festive element was not absent.

The Greek festivals were held in honour of national heroes; of gods connected with the fruits of the field, such as the Dionysia, Lenaea, and Eleusinia; and of the tutelary deities of Athens, such as the Panathenaea. The four great games—Isthmian, Nemean, Olympian, and Pythian—set the seal on the national unity. At Rome each family kept the festival of its domestic gods, the Lares and Penates; the public festivals were under the control of the state—festivals in honour of the tutelary deities of Rome, Romulus, Mars, and Quirinus, and of the divinities who presided over the crops, the fields, and boundaries, such as the Cerealia, Lupercalia, Saturnalia, and Terminalia. The public games (*ludi*) were also national festivals. (See *Feriae*; *Ludi*.)

#### Religious Festivals

Religious festivals are days set apart for rest, thanksgiving, and special observance. Some are fixed, as Christmas; others movable, as Easter. In the Christian calendar the greater festivals are called red letter days; while the lesser are known as black letter days.

Among the Jews such days are regarded as days appointed by God for meetings with His children. They include Passover, or Unleavened Bread, Nisan 15–22; Pentecost, Sivan 6; Trumpets, or New Year, Tishri 1; the Day of Atonement, or Great Sabbath, observed on Tishri 10, by complete rest and fasting, the only fast not postponed by the occurrence of the Sabbath; the Tabernacles, or Ingathering of the Harvest, Tishri 15–22; Jubilee, at the end of every seven Sabbatical Years; Purim, etc.

In the Christian Church the earliest festivals were the love feasts or Agapae (*q.v.*). Confusion has been caused by disregard of

the fact that both authorship and date of festival homilies are uncertain. Until the beginning of the 4th century, record exists only of Easter and Pentecost, though as each Friday was a fast in remembrance of the Crucifixion, so each Sunday was a festival in remembrance of the Resurrection. The feast of the Nativity was observed about 300; Christmas, Epiphany, and Ascension Day were added later.

#### Saints and Martyrs

Days in memory of the Apostles were next observed, and were followed by observance of days devoted to the memory of saints, of the Purification of the Virgin Mary, the Annunciation, the nativity of S. John the Baptist, the Circumcision, the death of martyrs, the transfer of their relics or the consecration of churches dedicated to them. Many Christian festivals are of local origin, some adapted from Jewish and pagan practice, and they increased in number during the Middle Ages. In the Roman Catholic communion, feasts are divided into doubles, semi-doubles, simples, etc., according to the offices appointed for them.

Inclusive of Sundays, festivals in the Anglican calendar number 149; of these the principal have proper collects, epistles, Gospels, and lessons, and some have a proper preface at Holy Communion and proper Psalms. The movable festivals which depend upon Easter are Septuagesima, Rogation Sunday, Ascension Day, Whit Sunday, and Trinity Sunday. In Great Britain public observance of Church festivals, apart from Easter, Whitsun, and Christmas, has fallen into abeyance; formerly all were made the occasion of some difference in the ordinary daily life of the people

#### Bairam and Ramadan

The chief festivals among Mahomedans, whose rest day is Friday, the day on which Mahomet was born, are the Feast of Bairam, that of Sacrifices, and that following the fast of Ramadan. The Hindus have their festivals, as that of Siva; and among certain tribes of North America is observed a festival called the Day of the Dead. The French Revolutionary calendar included five festival days, dedicated respectively to Virtue, Genius, Labour, Opinion, and Rewards, all in September. See Calendar; Prayer Book; articles under the name of each festival or saint; consult also Church Festivals, A. J. Maclean, in the Prayer Book Dictionary, 1912.

**Festival of Britain.** See N.V.

**Festubert.** Village of France in the dept. of Pas-de-Calais. It is 3 m. W. by N. of La Bassée and was prominent in the First Great War. There was an engagement here between the British and the Germans, Nov. 23–24, 1914. On the night of Nov. 23. the Germans had carried up a sap close to the Allied trenches, E. of Festubert, which were held by troops of the Indian corps. When day broke next morning the German infantry poured a storm of bombs

Festubert. Plan of the country over which were fought the battles of Nov., 1914, and May, 1915

and hand-grenades into the most advanced British trenches. They followed up this bombardment with an attack, and penetrated into the British trenches.

In the afternoon Sir J. Willcocks, commanding the Indian corps, ordered the original line to be recovered and held at all cost. All available British guns were directed to shell the trenches that the Germans had captured, as preparation for a British counter-attack, which was to open at 4.30. The infantry had to advance over snow-covered ground and they were received with violent machine-gun fire. But after hard and continuous hand-to-hand fighting, the ground lost was recovered.

**Festubert, BATTLE OF.** Fought during the First Great War, May, 1915. To assist the French operations in Artois and at Arras, where Foch was attacking, the British

First Army (Haig) was ordered to take the offensive on a front N.W. of La Bassée, from Laventie to Richebourg l'Avoué, against the German works on the Aubers Ridge. On the N. portion of this front the 4th corps (Rawlinson) attacked; on the S., the Indian corps (Willcocks) and the 1st corps. On May 9 the infantry advanced after a 40-min. bombardment, but found that the Germans were perfectly prepared, and that their wire had not been cut or their defences demolished by the artillery. The attack failed with heavy British losses. The total of killed, wounded, and missing exceeded 12,000, without any result, except that the Germans were held down in the section of attack. The failure was due to the weakness of the British artillery.

Nevertheless, French decided to resume the attack, extending it S. to Festubert. On May 15 the British once more assaulted, late in the night, after a prolonged artillery preparation. The troops engaged were the Indian corps on the British left, with the 2nd division at Givenchy and the 7th at Festubert. The Canadian division was placed in support. The 2nd division broke into the German trench system, carrying it for about half a mile, and the 7th division, attacking E. of Festubert, took another section of the German line, but between these two indentations the Germans could not be dislodged. They counter-attacked in the night of May 16, and forced back the 2nd division slightly, though most of the ground won was held. On May 17 the British, both from N. and S., assaulted the German wedge, 1,000 yds. long, between the two dents, and cleared it.

The trench battle continued on the following days; the British were much hampered by wet weather and insufficient ammunition, but ground was slowly gained, always at the price of heavy sacrifices. On May 20-21 the Canadians took up the work of the 7th division before Festubert; on May 25 the 47th London Territorial division was put in on the British right at Givenchy, and captured a section of the German line there, which was successfully held. The battle brought little result, as the capture of some thousands of yards of trenches was no compensation for the heavy sacrifices incurred. In killed, the British loss was 3,620, wounded, 17,484; missing, 4,321

H. W. Wilson

**Festus.** Poem by Philip James Bailey (*q.v.*). First published in 1839, it was added to and otherwise altered during 50 years until in its

final form, 1889, it consists of about 10,000 lines. A variant of the Faust legend, illustrating the ultimate triumph of good over evil, its scenes take place in Heaven and on the earth, and though it introduces "the three Persons of the Trinity as interlocutors in its wild plot" in a way which many readers resented, it has frequent terse and happy lines which have become familiar quotations.

**Festus, Porcius** (d. A.D. 62). Procurator of Judaea in succession to Felix, about A.D. 58. He heard, in the presence of Herod Agrippa II and Berenice, the case of S. Paul, whom he sent to Rome for trial (Acts 24-25; Josephus's *Ant. of the Jews*, xx, 8; Wars, ii, 14). He is said temporarily to have suppressed the Sicarii or Assassins, and was, if cynical, inclined to justice. He is introduced in a powerful short story, *The Procurator of Judaea*, by Anatole France

**Festus, Sextus Pompeius** (3rd century A.D.). Latin grammarian. He was the author of an abstract of the important work by Marcus Verrius Flaccus, *On the Meaning of Words*, containing an alphabetical list of obsolete words, together with valuable information concerning old state institutions and ceremonial. Part of it (M-T) has been preserved in the abstract of Festus and a further epitome by Paulus Diaconus (8th century), which is complete.

**Feth Ali Shah** OR **BABA KHAN** (1762-1834). Shah of Persia. Nephew of Aga Mohammed, he came to the throne in 1798, and threw himself into a contest with Russia to recover Persia's lost Caucasian territories. This brought him into conflict with Britain in 1812, and by the treaty of Gulistan, 1813, Feth Ali was forced to cede Georgia and seven adjacent provinces to Russia. War with Turkey

Fetichism. 1. Bondu witches or devils from Sierra Leone. 2. Man of Angola worshipping two fetishes. 3. Natives of the Sierra Leone hinterland with their fetish. See next page.

followed, 1821–23, but neither side gained material advantage. He died at Ispahan, Oct. 20, 1834.

**Fetishism** (Lat. *factitius*, artificial). Belief that the services of a spirit may be appropriated by the possession of its material embodiment. The 15th century Portuguese navigators applied to the sacred objects of the West African negroes the term *feitiço*, which they used of their own amulets. There is, however, a radical distinction between a fetish, which is a subservient spirit in its shrine, and an amulet, which—as in a modern mascot—is merely an instrument of spirit service. So also a fetish is not a god or even a divine image, and fetishism is not idolatry. The term as defined above conveniently describes a phase of the magic-religious life of negro Africa, and an analogous though not identical one of that of aboriginal America.

The fetish spirit may be bodiless or a disembodied soul; it may reside in a shell or a tooth, a hoof or a horn, a bead or a rag. The choice of an object as a fetish is often determined by its unusualness; the Mendi people consecrate to the same use rough soapstone statuettes (British Museum) found in caves abandoned by an earlier race. In the heart of Africa there is a tendency to turn a shapeless stone or a post—by a dab of paint or by crude chiselling—into human semblance. But the fetish is treated as a genie or guardian spirit, rather than as a superior. It is consulted or implored, praised or reproached, treasured or discarded. Its special “medicine” is discovered by experiment; the strings of *wongs* hung about the neck, over the hut door, at the village entry, have their several potencies, giving health, success, children or rain. (See illus. p. 3313.)

Among the American Indians, spirit-possessed objects are employed in an analogous way. With the Zuni, objects bearing or made to bear an animal semblance are highly prized, especially when consecrated by long tribal tradition. Here, however, a totemic aspect is observable; some objects once classed as fetishes are now perceived to be totems. The Amerind fetish usually differs from the African in possessing an impersonal power which the Iroquois call *orenda* and the Algonquins *manito*. (See Totemism.)

In psychology, the word fetishism is used to describe an abnormal condition in which the sufferer is obsessed by the attach-

ment of sexual significance to everyday objects having no direct sexual association.

**Fetter Lane.** London thoroughfare linking Fleet Street with Holborn. First mentioned in 1612 and once a way leading to gardens, its name is variously derived from *faitours*, vagabonds; and *feutriers*, felt-makers. The town hostel of the bishops of Norwich was once here. On the W. side is an entrance to Clifford's Inn (*q.v.*), with the Record Office and Breems Buildings, containing Birkbeck College, beyond. In Fleur-de-Lis Court, the scene of Mrs. Brownrigg's murder of her apprentice, Mary Clifford, in 1767, is Newton Hall. Buildings in the middle part of Fetter Lane were destroyed in air raids in the Second Great War.

**Fettes College.** Scottish public school. Founded with money left by Sir William Fettes (1750–1836),

Fettes College arms

lord provost of Edinburgh, it was opened in 1870, on a site near Inverleith Park, Edinburgh. It is now governed under a scheme dating from 1886. It possesses a fine range of buildings and laboratories, gymnasium, playing fields, etc. Four boarding houses and a school house accommodate 350 boys.

**Feu.** In Scotland, land held of a feudal superior on terms involving the payment of a perpetual rent called a feu duty. Land is usually feued for building purposes, the vassal (buyer) undertaking to build. A feu thus resembles a building lease in England.

**Feuchtwanger, Lion** (b. 1884). German writer, born in Munich, July 7, 1884. His first novel was *Jew Suss*, published in 1925 and trans. into English by Willa and Edwin Muir in 1926. It achieved remarkable success, and was made into a play and a film. The Ugly Duchess appeared in 1926, trans. 1927. Being a Jew, Feuchtwanger was compelled to leave Germany after the Nazis' advent to power in 1933, and lived in France, but in 1940 was placed in a concentration camp. He escaped to the U.S.A. His later works included *Exile*, 1939; *Paris Gazette*, 1940; *The Day Will Come*, 1942.

**Feud.** Word meaning a state of animosity, generally between two parties. It carries the idea of continuous hostility. A notable instance is the feud between the Guelphs and Ghibellines, and there

are instances among the Scottish clans, e.g. between the Campbells and the Macdonalds. See *Vendetta*.

**Feudalism** (late Lat. *feudum*, A.S. *feoh*, cattle, property). Name given to the social and political structure or organization which grew up on the ruins of the Imperial Roman system in Western Europe during the early Middle Ages. Universally established in its main features by the end of the 11th century, on its political side it was by the 16th century yielding to the effective concentration of the sovereign authority in the hands of supreme central governments.

It was based upon tenure of land. According to the lawyers, every foot of soil was actually the property of the king. Estates had been granted by him to his servants upon recognized conditions. On those conditions the king's “men,” “barons,” “tenants-in-chief,” “vassals,” held their lands from their overlord the king. They in their turn had granted portions of their estates upon like conditions to their own men or vassals. The actual occupants of the soil also held their plots of land upon conditions, from their overlord. Except the king, every holder of land was someone's vassal.

The primary condition of holding land was the rendering of military service to the immediate overlord; at the bottom of the

Fettes College, Edinburgh, from the south  
J. C. Inglis

scale agricultural or other kinds of service took the place of military service. The vassal rendered homage to his overlord, taking the oath of allegiance and service to him as his man, the lord taking corresponding oath to be “true lord and protector” to his man, the whole system being based upon the recognition of mutual obligations. Since the small landholder was not strong enough to protect himself against a powerful neighbour, and could hardly appeal to a distant overlord for protection it was customary for the small men to “commend” themselves to the

powerful—that is, to surrender their land (since it was alienable) to a lord, from whom they received it back as his tenants or vassals. Custom established the right of hereditary succession in various forms, and the claims a lord was entitled to make upon his tenants.

Broadly speaking, on the continent of Europe, it was generally held that the vassal owed allegiance only to his immediate lord, the result being that the king's great vassals, dukes or counts, could, if they chose to resist him, call upon their own vassals to serve against the king; the royal power depended in effect on the loyalty of the great vassals who individually, or by combination, were strong enough to defy him. Thus when a duke of Aquitaine, a vassal of the French crown in respect of Aquitaine, happened also to be king of England in respect of which he was independent of the French crown, he was able singly to defy his overlord; so also when one person was at once duke of Aquitaine, duke of Normandy, and count of Anjou.

In England the feudal system was not accompanied by an equal danger, because until the 15th century no single feudatories held sufficiently extensive domains to be strong enough to defy the crown except by means of widespread combination. Also, in England, the doctrine prevailed from the first that allegiance to the overlord prevailed over allegiance to the immediate lord. The last remaining relics of feudalism were abolished by the Law of Property Act, 1925. See Manor; Villeinage; consult also Constitutional History of England, W. Stubbs, 1897.

**Feu de Joie** (Fr., joy-fire). Running fire of musketry used generally on occasions of rejoicing. Ranks of soldiers fire one after another, beginning on the right of the front rank and continuing from the left of the second rank, etc.

**Feuerbach, Ludwig** (1804-72). German philosopher. Born at Landshut, Bavaria, July 28, 1804.

Ludwig Feuerbach, German philosopher

he attended Hegel's lectures at Berlin, and became a tutor at Erlangen. He abandoned teaching for a literary career in consequence of the excitement caused by his *Thoughts on Death and Immortality* (published anonymously 1830), in which he denied the im-

mortality of man. Subsequently inclining towards atheism, he declared the reconciliation of faith and science to be impossible, and in the place of theology substituted anthropology. The body is the very essence of man; the idea of a superhuman power is a fiction of man's own imagination. Man is only what he eats. Sensuous enjoyment is the supreme good, but only attainable by man as a member of society. He died near Nuremberg, Sept. 13, 1872. His other works include *The Essence of Christianity*, 1841, Eng. trans. M. Evans, 1854; and *The Philosophy of the Future*, 1843.

**Feuillants.** Religious order that flourished in France from the 16th century. It was an offshoot of the Cistercians, and the name originated in their monastery at Feuillant, near Toulouse. The abbot there, Jean de la Barrière, got into trouble with the authorities, so with a following he migrated to Paris in 1587, and founded the new order, one adopting a stricter form of life. A home was given to them in Paris by Henry III, and in 1589 they were recognized formally by the Pope. A later pope divided the order into two branches, French and Italian. The French kept the original name, and at the Revolution had in France 24 monastic houses, including one in the Rue St. Honoré, Paris.

**Feuillants.** Name of one of the parties that sprang up during the French Revolution. It was given to the members of a club because they met in the building in Paris formerly occupied by the religious order bearing this name. They originated with some Jacobins who, in 1791, refused to ask for the deposition of Louis XVI, and thereafter they formed the moderate wing of the revolutionary party.

They wished to maintain the constitution and to set up a stable government, and at the outset they called themselves the Society of Friends of the Constitution, but they never secured any great amount of support from the populace, although they were the largest party in the Constituent Assembly. Sieyès, Barère, and Lafayette were perhaps the most prominent members. Their wealth and their conservatism brought them under the suspicion of the extremists, and, after the rising of Aug. 10, 1792, their names were published as enemies of France. This put an end to their activities, although the name was still used to describe men holding moderate opinions.

**Feuillet, OCTAVE** (1821-90). French novelist and dramatist. Born at St. Lô, in La Manche, Aug.

11, 1821, he became an assistant to Dumas the elder. When he started on independent work he soon achieved considerable popularity with plays and with the novel, *Le Roman d'un Jeune Homme Pauvre*, 1858; this was followed by the

mystical romance *Histoire de Sybille*, 1863. In 1862 he was elected to the Academy, and was later made librarian at Fontainebleau. *Monsieur de Camors*, 1867; and *Le Journal d'une Femme*, 1878, were the more notable of his later works. His stories are characterized by a blend of romanticism and realism. He died in Paris, Dec. 29, 1890.

**Feuilleton** (Fr., leaflet). French word for the part of a newspaper, usually the lower part of a page, devoted to gossip, literary, artistic or dramatic criticism, and especially serial fiction. The practice, though not the name, has been traced to the section in Defoe's *Review* headed *Mercur Scandale*, but the *feuilleton*, as at present understood, originated in the *Journal des Débats* in the early years of the 19th century.

**Fever** (Lat. *febris*). Condition of the body, the most characteristic feature of which is a rise of temperature. Accompanying symptoms are increase in the pulse-rate, headache, thirst, and, in the early stages, sensations of chilliness which in severe cases may amount to fits of acute shivering or rigors. The skin is usually dry at first, but later there is profuse sweating, and the skin is hot and flushed. The urine may be diminished in amount and is highly coloured. The tongue is often coated, and in children vomiting is frequent. The normal temperature of the body in health varies between 98° and 99° F. Up to 102° F. the fever may be spoken of as "moderate." Temperatures of 105° or 106° are high, and above 106° the term *hyperpyrexia* may be employed. A temperature of 107° F. is very grave and recovery is improbable.

The cause of fever is most often the circulation of a poison in the blood, this toxin upsetting the temperature centre in the brain, and in most cases the poison is a product of bacterial activity of an acute infectious disease. It is now recognized that the rise of temperature indicates the reaction

of the body against the poison in the blood, and, provided it does not reach a dangerous height, it is to be regarded as a beneficial process. The treatment of fever depends upon the disease with which it is associated. Over-high temperatures may be reduced by cold sponging, or the application of an ice-pack.

Certain clinical terms are used to describe various types of fever. Continued fever is the condition in which the fever remains persistently high; in remittent fever there are daily fluctuations of two degrees or more; and in intermittent fever the increased temperature is only present during part of the day. In malaria, when there is a daily rise of temperature, the condition is termed quotidian; when the rise occurs on alternate days the fever is said to be tertian; and when two days elapse between the paroxysms it is quartan. See Scarlet Fever.

**Feverfew** (*Matricaria parthenium*). A perennial herb of the family Compositae. A native of Middle and S. Europe, it has small, clustered, daisy-like, yellow-centred, white flower-heads. The leaves are deeply cut into toothed oblong segments. The whole plant has a bitter, tonic smell, and was used as a rustic medicine in slight fevers. The name, formerly spelt

Feverfew. Plant and flower of this medicinal herb

feverfuge, is derived from Lat. *febrifugus* (febris, fever; *fugare*, to drive away).

**Fever Hospital.** Hospital for the reception of patients suffering from infectious diseases, e.g. scarlet fever and diphtheria. Such a hospital should be built on a site with a dry subsoil and good fall for drainage. It should be outside the town which it serves but with good facilities for access, and there should be ample grounds. There should be a detached administrative block, separate

wards for patients suffering from different diseases, and out-buildings such as laundry, stores, mortuary, and disinfecting chamber.

In the wards of hospitals the minimum floor space should not be less than 144 sq. ft., and the minimum cubic space 2,000 cubic ft. per head, the system of ventilation providing that air is changed three or four times an hour. A system of one-storeyed pavilions is the best. These should be connected with each other by corridors open to the air. Isolation hospitals for smallpox require a larger space around them than hospitals for other infectious diseases. See Hospital.

**Fez or TARBUSH.** Close-fitting cap of felt with a flat top, usually red with a black tassel. It was worn chiefly by the Turks with or instead of a turban (q.v.). The name comes from Fez, in Morocco, where these caps were originally made. See Cap colour plate, facing p. 1705.

**Fez or FAZ.** City of Morocco, and the northern capital. It is situated in a valley about 100 m. E. of the port of Rabat (q.v.), and is one of the sacred cities of Islam. The city, surrounded by ancient walls, is picturesque, and contains the Mosque of the Cherubim or of Muley Edris, to which is attached a Mahomedan university, once the centre of learning in N.W. Africa, with a library containing some 30,000 MSS. The city, which was founded in A.D. 808, is connected with Rabat by a light railway opened 1915. Pop. 144,424.

**Fezzan.** Country occupying the S. portion of the N. African colony of Libya. It was occupied by Italian troops towards the end of 1913. Fezzan extends some 400 m. N. and S., and 300 m. E. and W., and belongs to the desert region. The inhabitants are mostly Mahomedans belonging to the Sunnite sect. The chief oases are Ghat in the extreme S.W. and Murzuk. During the campaign of the Second Great War in N. Africa, it was announced on March 6, 1942, that Free French forces from Equatorial Africa had captured three Italian posts in Fezzan after a march of 900 miles. In Dec. Free French motorised

columns again invaded Fezzan, and advancing N. took Ouin-el-Arameb, the main Italian outpost, on Jan. 6, 1943. The conquest of the territory was completed by the capture of Murzuk on Jan. 12.

**Ffrangcon-Davies, GWEN** (b. 1896). British actress. Daughter of the singer David Ffrangcon-

G. Ffrangcon-Davies, British actress

Davies, she was born in London, Jan. 25, 1896, and educated at Hampstead. She sang soprano lead at the Glastonbury festival, 1919-20, and then scored her first great success as Etain in The Immortal Hour. An actress of unusual emotional range, she created the part of Eve in Back to Methuselah (q.v.), 1923, and became famous by her portrayal of Elizabeth Moulton-Barrett in The Barretts of Wimpole Street, 1930. Other memorable parts included

Fez. A street scene in the old part of the city

those of Anne of Bohemia in Richard of Bordeaux, 1932; Mary Stuart in Queen of Scots, 1934; Mrs. Manningham in Gas Light, 1939. In the Second Great War she toured S. Africa with Marda Vamne.

**Fiacre** (Fr.). Name of a saint and of a hackney carriage. The saint, also known as S. Fiachrach, a native of Ireland, died at Breuil, near Paris, about 670, and is commemorated on Aug. 30. Outside the Hotel de S. Fiacre, in Paris, in the 17th century, was the first stand for hackney carriages, and hence, it is supposed, is derived the application of the name fiacre to the vehicle. See Cab.

**Fianna.** In early Irish legend, the militia of Ireland, under the leadership of the warrior Finn, later known as Finn mac Cumhal. Their feats bear resemblance to

those of the Arthurian Knights of the Round Table. Cailte, the swift runner, and Oisín (Macpherson's Ossian), son of Finn, were prominent members of the Fianna. In later legend they appear in the reign of Cormac mac Airt, an Irish king of the 3rd century A.D., by whose son Coirpre they were finally quelled at the battle of Gabra, 283. The Anglicised form, Fenians, gave its name to the Fenian Brotherhood, an Irish political organization founded in the 1840s.

**Fianna Fáil** (Soldiers of Destiny). Irish political party formed by Eamonn De Valera (*q.v.*) in 1926, when he broke away from Sinn Féin and the I.R.A. The party entered the Dáil in the second general election of 1927; in 1932 it achieved its first majority and came to power, and its majority subsequently increased until it held in the 1947 Dáil a total of 76 seats against 27 of Fine Gael. After the 1948 elections it still led with 68 seats, but lost its majority and was voted out of office. Fianna Fáil's period of power was marked first by the abolition of the oath of loyalty to the British crown. Later it abolished the post of governor-general, reconstituted the senate, and introduced the constitution of 1937 in which the state was named Éire. *See* Éire.

**Fiar**. In Scots law, name given to the ultimate owner of an estate, the one in whom the ownership is really vested. The *fiar* is, therefore, the opposite of the life renter.

**Fiat** (Lat., let it be done). Term used in English law for a short order, usually permitting something to be done, made by a judge or high official. Thus a judge's order is required before a newspaper can be prosecuted for libel.

**Fiat** (abbrev. of Ital. *Fabbrica Italiana Automobile Torino*). A motor, aircraft, and general engineering works at Turin, Italy. Fiat aircraft and aero-engines equipped a large proportion of the Italian air force in the Second Great War; the fighters that escorted the sole Italian raid over Great Britain on Nov. 11, 1940, were of the Fiat C.R. 42 type. The works were frequently bombed by the R.A.F., one of the earliest raids being on Nov. 8, 1940, by bombers making a non-stop flight from England of 1,600 m. Another heavy raid was on Jan. 12, 1941; and on Sept. 9, Stirlings and Halifaxes delivered a low altitude attack. The first 8,000-lb. blockbuster used by the R.A.F. was dropped on the Fiat factory on Nov. 2, 1942.

**Fibiger, JOHANNES** (1867–1928). Danish pathologist. Born at Silkeborg, Jutland, April 23, 1867, he was educated in Denmark and attended medical schools in Germany and Austria. He turned his attention to cancer research, was president of the international conference for cancer, 1913–1920, and was awarded the Nobel prize for medicine in 1926. He died at Copenhagen, Jan. 30, 1928.

**Fibre** (Lat. *fibra*, filament). Term used for threadlike construction or appearance of many substances. Hair, wool, silk threads of the cocoons of silkworms, parts of leaves, bark of certain trees, grasses, etc., are all fibres. Though under certain conditions some metals exhibit a fibrous construction, it is difficult to separate the fibres, but occasionally metals spun into fine threads are spoken of as metal fibres, as also is spun glass. With the exception of asbestos, the fibres of which are woven into a kind of cloth, the fibres of commerce can be conveniently divided into two classes, animal and vegetable.

Animal fibres are the wool and hair of animals, and the silk of insect cocoons. Though comparatively few animals produce commercial fibre, these few are of great importance. Sheep's wool, mohair from the Angora goat, the hair of the llama and alpaca, and those of the cow, camel, and rabbit—the last for felts—and horsehair are the chief commercial animal fibres, and their uses are dealt with under their respective headings.

Vegetable fibres constitute a large and important class, and are put to a greater variety of uses than animal fibres. Flax, China grass or ramie, hemp, jute, cotton, raffia, sisal hemp, tampico, coconut, esparto grass, and Mexican whisk or broom root are among the chief vegetable fibres.

The grasses or fibres of S. America and Africa are collected and sent over to importers in the British Isles, who sell them to the dressers, who in turn cut the fibre to different lengths for various uses and sell it to brush-makers. Brush-making is an important industry, and an enormous amount of fibre is used, some brush-makers dressing and cleaning their own raw material. The fibre is cleaned of all dirt, cut, and hackled to make it clean and strong; then cut again, dyed if necessary, steamed and so made straight, and then it is left to dry hard.

Palmyra fibre, commonly known as bassin in the brush trade, is a

strong, medium-sized fibre, and is often dyed to look like Bahia piassaba, which is the best material for street brushes, etc. Mexican fibre, of which there are two kinds—tula, which is short, and jumava, a longer variety—is a white fibre which, when dressed, is used for toilet hair brushes, nail brushes, etc. Coco fibre from the husk of the coconut is used for making mats, and also for domestic brushes and brooms.

The principal use of coir yarn is for thatching, though it is sometimes used for large mats. Piassaba, the most important fibre in the brush trade, is used for all kinds of brushes and brooms, and is found chiefly in Brazil and W. Africa. It is also largely used in S. America for rope-making. Kitool, from Ceylon, is the aristocrat of fibres; it is polished and treated with oil, and is expensive. It is used for making fine brushes and also for the manufacture of ropes of good quality.

#### Various Fibres for Many Uses

Such brushes as dandy brushes for horses are generally made from Mexican fibre. Animal fibre—horsehair, badger's hair, sable, and camel's hair—is extensively used in brush-making. Cheap fibres which pulp easily are used for paper-making. Among them are esparto grass, the paper mulberry (the bark of which is converted into paper extensively used in Japan), cotton grass, and Decan hemp. From the leaves of *Carludovicia palmata* is obtained the fibre from which Panama hats are manufactured; from *Cibotium barometz*, a fern growing in the Sandwich Islands, comes a variety of vegetable silk used for stuffing upholstery work, especially in the U.S.A.; and from *Eriodendron anfractuosum* comes kapok, a soft, silky, elastic fibre used in upholstery, for the stuffing of cushions, seats, etc. *See* Asbestos; Cotton; Flax; Hemp; Jute; Paper; Rope; Silk; Sisal.

**Fibrin** (Lat. *fibra*, filament). Threads of solid proteid formed in the process of coagulation of blood. The fine threads entangle the corpuscles of the blood and, gradually shrinking, squeeze out the fluid part of the blood or plasma, the solid mass of fibrin and corpuscles forming the clot. *See* Blood.

**Fibroid**. A tumour composed mainly of fibrous tissue, more correctly called a fibroma (*q.v.*). A common tumour of the uterus is spoken of as a fibroid, but is really developed from the muscular tissue. *See* Uterus.

**Fibrolite.** Fibrous massive variety of sillimanite. It has the same chemical composition as andalusite and kyanite ( $Al_2SiO_5$ ).

**Fibroma.** Tumour composed mainly of fibrous tissue. Soft fibromata most frequently develop from the connective tissue of the skin, and may form pedunculated outgrowths. Hard fibromata are found in connexion with the periosteum or tissue covering the surface bones, the ear, and other parts.

**Fibrositis.** Disease of an inflammatory nature affecting the fibrous tissue or fascia which surrounds muscles and extends between the muscular fibres. Pain is the most prominent symptom. The causes of the disorder are exposure to cold and wet, sudden chilling after heavy labour, and sometimes a blow. Persons of gouty tendency are most likely to be affected. See Lumbago; Pleurodynia; Stiff Neck.

**Fibrous Tissue.** Tissue composed chiefly of bundles of fine white fibres. It is found in tendons, ligaments, fascia, and the deeper layers of the skin.

**Fibula** (Lat., buckle). Outer of the two bones which form the skeleton of the lower leg. It is a long, slender bone, firmly attached to the tibia by ligaments at its upper and lower extremities. The lower extremity forms the external malleolus or bony protuberance on the outer side of the ankle, and helps to form the socket in which the foot articulates with the bones of the leg. See Leg.

**Fibula** (Lat.). Brooch or clasp, especially of the early metallic ages. The neolithic bone pin, often made from the splint bone or fibula of a vertebrate animal, was imitated in bronze; when bent over until the looped head clasped the point the safety-pin resulted. Common in Italian pile-dwellings, and the early Aegean, it developed at Hallstatt a bolder bow, often much decorated. Under

Fibula. Merovingian bronze-gilt brooch set with garnets, 7th cent.

La Tène influence three further stages are traced, the catchplate being bent back so as to (i) approach, (ii) clasp, (iii) unite with the bow. This sequence serves to date iron-age antiquities wherever these types are found. Unlike these late-Celtic forms, the Roman fibula

was in two pieces. Anglo-Saxon types, sometimes betraying continental influence, mostly display native developments, especially in *cloisonné*. The choicest Gaelic examples came from Hunterston, Tara, and Aesica. They are now in Edinburgh, Dublin, and Newcastle respectively. See Brooch.

**Fichte**, JOHANN GOTTLIEB (1762–1814). German philosopher. Born at Rammenau, Lusatia, May 19, 1762, he left Jena university owing to poverty, and in Switzerland became acquainted with Kant's philosophy. The attention attracted by his *A Critique of All Revelation*, written while he was a tutor at Königsberg, helped him

Fibula. Diagram illustrating relative positions of tibia and fibula in the human leg.

to obtain the professorship of philosophy at Jena. In 1799, having been accused of atheism, he resigned his post and retired to Berlin, where he was allowed to lecture on philosophy. In 1807, when the French invaded Prussia, Fichte showed his ardent patriotism in his *Addresses to the German Nation*.

He died at Berlin, Jan. 27, 1814, from a fever contracted during the war of independence.

Fichte's system has been

*Johann Gottlieb Fichte*  
After Büry

called practical idealism, according to which the power of the will in the Ego is supreme. The Ego or self is a purely active being, which derives from itself the entirety of knowledge. It is to the Ego that we have to look for the explanation of everything. The Ego, feeling itself limited,

"posits itself" as determining the non-Ego. The counterpart of whatever belongs to the Ego belongs to the non-Ego. The Ego created the non-Ego; it creates nature and God. But God is not merely a creation of the Ego, but the absolute Ego, the infinite will of the universe, the source of the finite Ego, to which we must ever strive to become united. Fichte's most important work is *The Foundation of the Whole Doctrine of Knowledge*, 1795.

**Fichtelgebirge.** Mountain system of Germany. Its central nucleus is situated in N.E. Bavaria between the basins of the Regnitz and the Naad. The name is derived from the pine trees (*Fichte*), with which it is largely covered. From it flow the rivers Eger, Saale (to the Elbe), Naab (to the Danube), and Main (to the Rhine). The principal summits are Schneeberg (3,450 ft.) and Ochsenkopf (3,334 ft.). It has connexions with or ramifications into the Erzgebirge and the Thuringian Forest, and contained spas and pottery and china works.

**Fiction** (Lat. *fictio*, feigning). Term now applied almost wholly to prose romances or novels, although strictly it means anything that is feigned, and is applicable to any literary productions of the imagination. See Literature; Novel; Romance.

**Fiction, LEGAL.** Legal phrase denoting an assumption of fact without question of its truth, for the purpose of evading technical difficulties. Fictions occur in every system of jurisprudence. They have been invented to enable changes to be effected in the substance of the law while deferring to the wholesome imaginative reverence for its old symbols and formalities. Fictions of law are not allowed to be denied, their proper operation, according to Blackstone, being "to prevent a mischief, or remedy an inconvenience, that might result from the general rule of law," while further the maxim is invariably observed that no fiction shall extend to work an injury.

In England it was through fictions that the courts of king's bench, exchequer, and common pleas encroached on the previously distinct jurisdiction of one another. By the common law no mere civil action could be prosecuted in the king's bench, but plea of any civil action could be held there, other than actions real, if the defendant was an officer of the court, or in the custody of the marshal of the court, for a breach of the peace or any other offence; hence the fiction was introduced into the

pleadings that the defendant had been arrested for a supposed trespass, and so, being in the custody of the marshal, could be proceeded against for any other personal injury.

Similarly in the court of exchequer, personal actions were gradually admitted by the fiction that the plaintiff was the king's debtor, and was prevented from discharging his liability by the failure of the defendant to pay. By another fiction, actions for ejectment were made to serve the purpose of claimants to land, the names John Doe and Richard Roe being employed as those of an imaginary lessee and wrongful ejector.

Other fictions impose a conventional rule where exact facts are difficult to ascertain. *e.g.* the law takes no notice of fractions of a day, so that if a thing is to be done on a certain day, as payment of rent on quarter day, the whole day is allowed for its performance.

Again, in determining the exact moment at which a person becomes 21, the law, in general, disregards fractions of a day. This has a curious result. The law will not inquire as to the particular moment in the day at which the infant was born, and therefore considers that 21 years have elapsed since his birth at the close of the day preceding the 21st anniversary. There is, however, a legal maxim that a day that has begun is regarded as completed; so that at the first moment of the day preceding the infant's birthday, he becomes 21.

**Fiddle.** Old English name for the violin and its ancestors. It denoted originally any stringed instrument played with a bow, but came in time to be applied chiefly to the smaller sizes of such instruments. Fiddle, with viol, is connected with the Latin *vitulari*, to celebrate a feast.

**Fidei Commissum** (Lat. *commissum*, entrusted; *fidei*, to good faith). Term of Roman law. By the civil law of Rome, a citizen could neither make a foreigner his heir nor leave him any legacy. As foreign settlers (*peregrini*) became more numerous in Rome, citizens often desired to leave their property, or part of it, to some foreign friend. The only way to do this was to leave the property to a citizen, asking him to carry out the testator's wishes, and hand the property over to the foreigner. At first it was entirely optional on the heir whether he carried out the request or not. It was left to his faith. But, in the end, *fidei commissum* became legally enforceable.

**Fidelio.** Opera in 2 acts by Beethoven. Listed as opus 72, this work was the composer's only opera. Based on Bouilly's *Léonore*—an heroic episode during the French Revolution—the libretto was recast by Sonnleithner, and the work, the sub-title of which was *Die Eheliche Liebe* (Wedded Love) was given in 3 acts at Vienna, 1805. Shortened and revised, it was performed the following year, but withdrawn by the composer. *Fidelio* was given in its present form at Vienna in 1814. It has been said that Beethoven in this work appears to forget the characters and lose himself in contemplation of a moral idea; albeit *Fidelio* must be considered important in the history of opera. The famous *Leonora* overtures were written for this opera: No. 2 for the first production, No. 3 for the revival, No. 1 for a projected performance at Prague, which never materialised. The *Fidelio* overture preceded the final revision of the opera in 1814.

**Fidelity Guarantee.** Contract by which a person or persons undertake to make good losses due to fraud or negligence on the part of another person occupying a position of trust. Banks and business houses frequently require a guarantee of this kind on behalf of such of their employees as handle large sums of money, and many insurance offices, in return for an annual premium, enter into guarantees of this kind. Guarantee societies exist for the same purpose. *See* Guarantee; Insurance.

**Fidenae.** Italian town of Latium. It was situated about 5 m. N.E. of Rome, on a hill between the Anio and the Tiber. Frequently at war with Rome, it was finally conquered 438 B.C., and destroyed in the year following. Thereafter, though rebuilt, it never became a place of importance.

**Fides.** In Roman mythology, the goddess held as symbolical of faith and honour.

**Fiduciary Issue.** That portion of the note issue of a central bank which, by law, is not required to be covered by gold. The adjective is used in the sense of "held in trust." Fixing a limit to a fiduciary issue was originally necessary because of the tendency of central banks to overissue their notes, which became valueless. In the Bank Charter Act of 1844 the Bank of England fiduciary issue was fixed at £14,000,000; when in 1928 the treasury note issue was transferred to the Bank of England, the figure was raised to

£260,000,000; by 1939 the permitted issue outside the gold backing was £400,000,000. The need to free all gold held, and subsequently acquired, for overseas purchasing during the Second Great War, coupled with the constantly rising demand for currency, led to repeated additions to the fiduciary issue, so that by 1945 the figure had risen to £1,400,000,000. After the war national expenditure was three times that of the last pre-war years, and the fiduciary issue was maintained at a high figure; in 1950 it was £1,300,000,000.

Power to raise or reduce the limit rests with the treasury in consultation with the governor of the Bank of England, so that adjustments can be made as economic conditions determine. Notes within the fiduciary issue are secured by government securities; it is thus upon these rather than upon gold that currency now rests.

**Fief.** Name given to an estate held under the feudal system. It was, therefore, one which was held on condition of rendering certain services to an overlord, and which in certain eventualities reverted to that lord. The word is sometimes rendered in English as *feu* or *fee*. From it come *feoffee*, the one who receives the estate, and *feoffment* (*q.v.*), the act of granting it to him. *See* Feudalism.

**Field.** Anglo-Saxon word, meaning the open country. It is now used for a piece of enclosed land *e.g.* a wheatfield, and by analogy we speak of a coalfield or oilfield. It is employed also in a military and sporting sense. In the former, field is a synonym for battle or battleground, *e.g.* the field of Waterloo. This use has many compounds, such as field ambulance, relating to war. In sport the field has various meanings, *e.g.* the horses in a race or the riders at a hunt meeting are the field; in betting parlance, the field signifies all those horses not quoted individually at odds, and in a sweepstakes all horses not drawn separately. Field sports are hunting, racing, and the like. Field events in athletics include putting the weight, throwing the discus, etc. *See* Cricket; Horse-Racing.

**Field.** In heraldry, the surface of an armorial shield on which charges are placed. The same term is applied to the body of a flag, *e.g.* the British white ensign is a red cross on a white field, with the union jack in a canton (*q.v.*).

**Field, THE.** London weekly journal devoted to all forms of sport, natural history, and

country life occupations. Founded Jan. 1, 1853, by Bradbury and Evans, it was first edited by Mark Lemon. Its prosperity dates from its acquisition in 1854 by Mr. Sergeant Cox, and the appointment in 1857 of J. H. Walsh ("Stonehenge") as editor. In 1928 it was acquired by Sir R. L. Harmsworth and Sir H. Harmsworth. B. Vesey-FitzGerald was editor 1938-46.

**Field, CYRUS WEST** (1819-92). American financier. Born at Stockbridge, Mass., Nov. 30, 1819, he made a fortune and retired from business at 33, when he became interested in the idea of the trans-Atlantic cable. In 1854 he organized the New York, Newfoundland, and London Telegraph co., and 10 years later persuaded the U.S. and British governments to confirm by soundings the existence of Telegraph Plateau in the Atlantic. The first cable was laid in 1859. Heavy financial losses necessitated Field's return to business, and he was an originator of the New York elevated rly. He died at New York, July 12, 1892. See Atlantic Cable.

**Field, EUGENE** (1850-95). An American poet and journalist, born at St. Louis, Mo., Sept. 2, 1850. During 1883-95 he contributed to the Chicago Daily News a column entitled Sharps and Flats. His poems include *A Little Book of Western Verse*, 1889, and *With Trumpet and Drum*, 1892, charming verses for children. His most attractive essays are collected in *The Love Affairs of a Bibliomaniac*, 1896. He died Nov. 4, 1895.

**Field, JOHN** (1782-1837). Irish composer. Son of a violinist, he was born in Dublin, July 26, 1782, and became an assistant in the London pianoforte shop of Clementi & Co. He made his debut as a pianist in London in 1794. In 1802 he accompanied Clementi to France and Germany and then settled at St. Petersburg as a teacher. He died at Moscow, Jan. 11, 1837. Field's nocturnes are reputed to have influenced Chopin in the writing of what was then a new form of composition. His seven concertos had a vogue, but are forgotten. Harty arranged a John Field suite in 1940.

**Field, MICHAEL.** Pseudonym adopted by two poets who worked in collaboration: Katherine Harris Bradley (born Oct. 27, 1846; died Sept. 26, 1914) and her niece Edith Emma Cooper (born Jan. 12, 1862; died Dec. 13, 1913). Their first joint work, *Bellerophon*, published under the names of Arran and Isla Leigh, appeared in 1881, and they made use of the

name Michael Field in 1884, when they published *Callirrhoe*. Later works included *The World at Auction*; *The Race of Leaves*; *Poems of Adoration*; *Cedar and Hyssop*; *Mystic Trees*. Consult biographies by M. Sturgeon, 1922; T. S. Moore, 1934.

**Field Allowance.** Emolument granted to an army officer on going into camp or taking the field on active service, in compensation for the extra expense of tent furniture, messing, etc. During the Second Great War the field allowance varied from 2s.-7s. 6d. a day for a second lieutenant to 10s.-£4 for a general officer, according to the theatre of operations. The highest field allowances were paid to officers serving in Burma.

**Field Ambulance.** Mobile unit of the Royal Army Medical Corps organized in companies to work with forward troops. Nowadays a field ambulance is completely mechanised and is staffed by 10 medical officers and 240 drivers, orderlies, and stretcher-bearers. It is equipped to receive casualties from the casualty clearing stations and has a mobile blood bank. The general principle of the field ambulance is to treat slight casualties which can be returned to their units, and to give primary treatment to serious cases pending their movement to a general or base hospital.

**Field Dressing.** Antiseptic dressing carried by officers and men of the British army and R.A.F. on active service. It consists of a pad of sterilised gauze, to which is fastened a length of bandage so that it can be securely fastened over a wound. The field-dressing is enclosed in a dust-proof wrapping and carried in a special pocket in the trousers or tunic.

**Fieldfare** (A.S. *feldfare*, field traveller). A bird of the thrush family (*Turdus pilaris*). Visiting

Fieldfare. Member of the thrush family, found in Great Britain

Great Britain in vast flocks in winter, it spends the rest of the year in Scandinavia and Russia. In plumage and general appearance it closely resembles the common thrush, but has not its vocal powers. It is seldom seen in

parties of less than twenty, and often the flock will exceed a hundred. It feeds upon grubs, small snails, and berries. When feeding it continually advances in one direction, and a flock of the birds appears to move forward in open order with almost military precision. Fieldfares nest in great colonies, and return year by year to the same site, the nests being usually built in pine woods.

**Field-glasses.** Small binocular telescope for viewing distant objects. The earlier field-glasses consisted simply of two short telescopes mounted side by side in a frame and focused by means of a screw. The telescopes were of the "Galilean" type, in which the object-glass is a convex lens which converts the parallel beam of light from a distant object into a convergent pencil of rays. The

Field-glasses. Diagram illustrating path of light in a prismatic field-glass

tube is a short one, and before the converging rays can come to a focus they pass through the concave eye-piece which transmits them to the eye as a parallel beam. In order that the images may be free from coloured fringes, it is necessary to substitute achromatic combinations for the simple lenses.

The advantage of this type of telescope for field-glasses lies in the shortness of the tube; its disadvantage in the narrowness of the field of vision. Rays from objects slightly off the direction in which the glass is pointed get lost inside the tube, and fail to reach the eye-piece. To avoid this defect, prisms were introduced into the tube to catch the aberrant rays and reflect them into the eye-piece. This was the origin of the modern form of field-glass, the prismatic binocular. There may be one object-glass or two, but in either case the entering pencil of rays is reflected twice or more between parallel prisms, and finally directed into the eye-piece. This arrangement gives a wider field than in the simple type of field-glass, but as a certain amount of light is lost at each reflection the field is not so bright. In fact, the prismatic binocular was rendered possible only by the invention of a glass for the prisms which reflected a specially large percentage of the light falling on it. See Telescope.

**Field Gun.** Mobile gun for use with troops in the field. That used by the British army in the First

**Field Gun.** Britain's 25-pounder in action. The standard gun for field artillery regiments

Great War was horse-drawn and sufficiently mobile to keep in touch with the advancing infantry. It had a calibre of 3.3 ins., fired a shell weighing 18½ lb. and had an extreme range of 9,000 yds. It weighed 1 ton 6 cwt., and the limber 15 cwt. Various types of field gun were developed for the British army in the Second Great War, but the most successful was the 25-pounder weapon, which became the standard gun for field artillery regiments. It had a calibre of 3.75 ins., an extreme range of 13,000 yds., and could be elevated to 45° and turn in its own length. The replacement of horse transport by mechanical traction has removed the limit to the size of field guns, and artillery up to 8-in. calibre now operates with troops in the field. *See Artillery.*

**Field Hospital.** Reception centre and clearing hospital for casualties removed from fighting areas by the field ambulance (*q.v.*). A field hospital, which was highly mobile and could move forward or back at short notice, was manned by the Royal Army Medical Corps (*q.v.*), one being attached to every division. When possible, use was made of existing buildings in the battle area, but in the campaigns in North Africa in the Second Great War the field hospital was accommodated in tents and marquees, which were carried by its own transport. A field hospital normally took 200-300 casualties, and was equipped with mobile operating theatre and X-ray equipment. It retained casualties only until their wounds had been dressed or emergency operations carried out, whereupon they were moved to a base hospital.

**Fielding, HENRY** (1707-54). English novelist. Born near Glas-tonbury, April 22, 1707, a scion of the Denbigh family, he was edu-

cated at Eton and at the university of Leyden, studying civil law. Coming to London about the age

of 20, he gave up his legal studies and began to work for the stage. He wrote a number of farces and other light pieces which have not lived. Called to the bar in 1740, he was appointed justice of the peace for Westminster in 1749 and proved a conscientious and painstaking

magistrate. Careless living, how-

ever, had undermined his originally strong constitution. He died at Lisbon, whither he had gone for his health, Oct. 8, 1754. His *Journal of the voyage*, a delightful work, was also his last.

Fielding's first novel, *Joseph Andrews*, appeared in 1742. It began as a deliberate caricature of Richardson's *Pamela*, then just published. As the narrative progressed, Fielding became interested in his characters; the caricature fades into the background, and the result is a human and lifelike story. Joseph Andrews was followed in 1743 by *Jonathan Wild*, though it seems probable that this grim portrayal of the career of a consummate scoundrel was written first. Then in 1749 came *Tom Jones*, which some critics regard as the greatest novel ever written.

*Fielding*  
From a print

Sophia, the hypocrite Blifil, the egregious humbugs Thwackem and Square, and the ingenuous Part-ridge are intensely lifelike. "That exquisite picture of human manners," declared Gibbon, "will survive the palace of the Escorial and the Imperial Eagle of the House of Austria."

Fielding's last novel, *Amelia*, 1751, is subdued in tone as compared with the boisterous high spirits of *Tom Jones*. It is to a

certain extent autobiographical, the original of the erring Captain Booth being Fielding himself. *Amelia* was the favourite novel of Thackeray, who gives a masterly appreciation of Fielding in his *English Humourists*. There are other *Lives* or studies by A. Dobson, 1907; G. M. Godden, 1910; W. L. Cross, 1919; H. K. Banerji, 1930; B. M. Jones, 1933; M. P. Willcocks, 1946. *See English Literature*; *Novel*.

**Field-lens.** Part of an optical instrument. The more complex forms of eye-piece used in optical instruments consist of more than one lens in order that chromatic aberration and other image defects may be reduced. In both the Ramsden and Huygens eye-pieces there are two plano-convex lenses, the one next to the eye being termed the eye-lens, and the other the field-lens.

**Field Madder** (*Sherardia arvensis*). Annual bristly herb of the family Rubiaceae. It is a native

**Field Madder.** Spray of foliage and flowers, and a detached leaf

of Europe, Asia, and the Canaries. Its trailing stems, a foot or more in length, spread from the root, and are clothed with whorls of sharp-pointed lance-shaped leaves. The lilac funnel-shaped flowers are about ½ in. across. It grows in cornfields and pastures.

**Field Marshal.** Highest rank in the British army, equivalent to admiral of the fleet in the Royal Navy and to marshal of the Royal Air Force. The first English field marshal was William, earl of Salisbury, who in 1214 was appointed by King John *mariscalcus* of his military forces. At that time the marshal was responsible for maintaining order in court and camp. The modern sense, dates from 1736, when George II conferred the rank on John, duke of Argyll.

**Field Marshal.** Badge on shoulder

Any officer on either the active or the retired list may be promoted field marshal without reference to seniority, but it is laid down that there shall not be more than eight field marshals on the active list. The honorary rank of field marshal in the British Army is sometimes conferred upon foreign kings. Colonels commandant of the Royal Artillery and Royal Engineers, and colonels of the King's Royal Rifle Corps and the Rifle Brigade are selected from the field marshals, who are also eligible for appointment as governors of the Tower of London and of Chelsea Hospital. Rank is indicated by crossed batons surrounded by a wreath and surmounted by a crown. With full dress a baton is carried.

**Field Mouse.** A name erroneously given to several small rodents, both mice and voles. It is

Field Mouse. Brown long-tailed  
*Apodemus*

correctly applied only to *Apodemus*, the wood mouse, otherwise called the long-tailed field mouse, a common pest in most parts of England, in gardens and hedge-rows, and in corn-stacks.

**Field Officer.** Military officer above the rank of captain and below the rank of general: *i.e.* major, lieutenant-colonel, colonel, and brigadier. Before the age of mechanisation, field officers of infantry regiments were always mounted. Field officers not having any company or squadron responsibilities are generally assigned to special duties, such as presiding at courts martial. A brevet major ranks as a field officer for the period of his brevet, but performs company duties as required. Normally sentries pay compliments to field officers by presenting arms. *See* Brigadier; Colonel; Major.

**Field of the Cloth of Gold.** Term applied to the meeting-place of Henry VIII and Francis I of France, June 7-24, 1520. The meeting took place near Guines, and the name was given to it on account of the magnificence displayed on the occasion.

**Field Punishment.** Punishment authorised by the Army Act to be inflicted on private soldiers

on active service in consequence of the lack of prisons or detention barracks. Field punishment No. 1, abolished in 1923, involved such restraint as is usual in cases of imprisonment with hard labour, and in addition the prisoner could for three days out of four be "attached to a fixed object," such as a tree or a gunwheel, with straps or ropes, for not more than two hours a day. This mode of restraint could not, however, be adopted for more than 21 days in all. *See* Court Martial.

**Fields, GRACIE** (b. 1898). Stage name of Grace Stansfield, British variety and screen actress. Born at Rochdale, Jan. 9, 1898, she made her stage debut as a child there, and appeared in London at the Middlesex music hall in 1915. Her broad, Lancashire humour, abundant vitality, and remarkably flexible voice rapidly endeared her to audiences, and she became the best known comedienne of the day, appearing in such revues as Mr. Tower of London, 1918-25; The Show's The Thing, 1929; Walk This Way, 1931. She made one appearance on the legitimate stage, in S.O.S. at the St. James's Theatre, 1928. In 1931 she made her film debut in Sally in our Alley. Her later films included Queen of Hearts, 1936; Stage Door Canteen, 1943; Holy Matrimony (based on Arnold Bennett's novel, Buried Alive), 1943; Madame Pimpernel, 1946. She was created C.B.E. in 1938. She married first Archie Pitt, and in 1940 the Italian-born film director Monty Banks (d. 1950) shortly before he became a U.S. citizen, remaining with him for some years in the U.S.A.

**Fields, W. C.** (1879-1946). American actor. Claud William Dukenfield was born at Philadelphia, Jan. 29, 1879. He first attained fame as a juggler, and played in various parts of the world; after the First Great War he appeared in revues and comedies in New York, *e.g.* Scandals, 1922; Poppy, 1925. Then he began his film career and developed into a character actor, specialising in studies of alcoholic and humorous eccentrics. His portrayal of Micawber in David Copperfield in 1935 was probably his finest achievement. Later films included The Big Broadcast of 1938; My Little Chickadee, 1940; The Bank Detective, 1941. He died Dec. 25, 1946.

**Field Train.** Name formerly given to the transport attached to fighting units for the conveyance of the stores, supplies, and baggage necessary for their subsistence.

The term field train has now been replaced by the names first and second line transport: first line transport carries ammunition and rations, second line carries baggage. In infantry regiments each platoon has its own truck for first line transport. *See* Royal Army Service Corps.

**Fieri facias** (Lat., cause thou to be made). Term of English law. It refers to a writ of execution directed to the sheriff commanding him to seize and sell sufficient goods of a person against whom a judgement has been obtained to realize the amount of the debt.

**Fiery Cross.** Charred sticks dipped in goat's blood and usually joined in the form of a cross, which fleet-footed retainers of the chief carried round among the Scottish clansmen to call them together in time of emergency. Disobedience to the summons rendered any man between the age of 16 and 60 liable to the extreme penalties of fire and sword. During the "Forty-five" the fiery cross made many circuits. A fine description of the custom is given in Scott's *Lady of the Lake*, Canto III.

**Fiery Serpent.** Name given to the serpents sent to the Israelites in the wilderness (Num. 21). They were probably sand snakes, called fiery because of the effect of their bite. *See* Snake.

**Fiescherhorn.** Mt. of Switzerland. In the Bernese Oberland (*q.v.*), near Grindelwald, its height is 13,286 ft. The ascent from the Bergli Hut by the Mönch-Joch needs the help of a guide.

**Fieseler.** A German aircraft manufacturing company, founded by Gerhard Fieseler in 1930. During the Second Great War it produced the Fi 156, or Storch, designed for communications and army liaison work. This was a small three-seater monoplane with a single 240 h.p. Argus engine. The high wing was fitted with slots and flaps that permitted a landing speed of 24 m.p.h., and, in still air, a landing run of 27 yds., and a take-off in 51 yds.

**Fiesole** (anc. *Faesulæ*). City of Italy, in the prov. of Florence. It stands on an eminence overlooking the valley of the Arno, 3 m. N.E. of Florence. It was one of the 12 Etruscan cities, and is enclosed by crumbling cyclopean walls. Its cathedral, founded early in the 11th century, contains many interesting paintings and sculptures. Straw-plaiting is carried on by the inhabitants. Here in 225 B.C. the Gauls defeated the Romans, and

Sulla's veterans formed a colony, later the headquarters of Catiline. For long an opulent city, its prosperity waned as Florence grew in power. It was damaged, but not seriously, in the Second Great War; military operations passed over it in Aug., 1944. Pop. 10,434. *Pron.* Feeay-zolay.

**Fife** (Fr. *fifre*, Ger. *Pfeife*, Lat. *pipare*, to chirp, pipe). Small flute used in association with drums to accompany military marching when a full band is not available. In a drum and fife band the chief melodic work is allotted to the B flat fifes, arranged to play in unison or in two or three parts; they are assisted in lower notes by larger flutes, in F and in E flat, and in the higher ranges by piccolos (*q.v.*) in F and in E flat. As the open key of all the flutes is called D, transpositions are reckoned from D, instead of from C as with most other instruments. For example, the first two bars of God Save the King, in key B flat, would be written as follows to secure a unison effect:

Piccolo in F.

Piccolo in E♭.

Fife in B♭.

Flute in F.

Flute in E♭.

and the actual pitch would be:

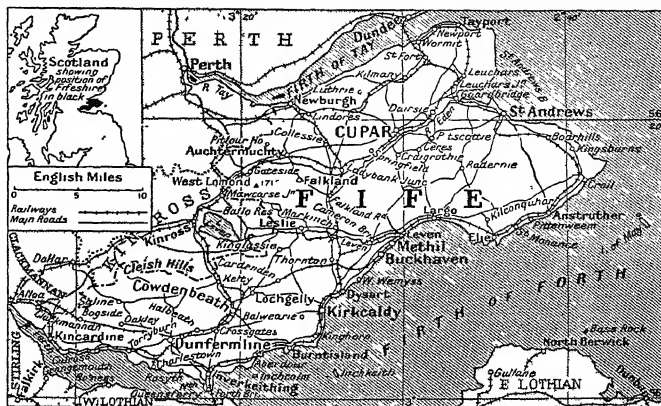

In fife bands the percussion instruments include side-drums, bass drum, cymbals, and triangle.

**Fife** or **FIFESHIRE**. Eastern maritime and peninsular county of Scotland. Lying between the Firth of Tay and the Firth of Forth, it covers 504 sq. m. The surface alternates between hill ridges and fertile and well cultivated valleys, the highest eminence be-

Fife arms

Fife. Map of the Scottish county between the Firths of Tay and Forth

ing West Lomond, 1,713 ft. There are several small lakes; the Eden and Leven are the largest rivers.

Nearly 75 p.c. of the soil is cultivated; wheat, barley, oats, and potatoes are raised. The mineral wealth of the county is large, represented mainly by coal around Cowdenbeath, but limestone, ironstone, freestone, and oil-shale are also worked. Most of the coast towns and villages engage in fishing, and the linen and floor-cloth manufactures are prominent.

The county of Fife returns four members to parliament, including one each for the Kirkcaldy and Dunfermline burghs. Cupar or Cupar Fife is the county town. St. Andrews is the seat of a bishop and an R.C. archbishop; has the oldest Scottish university; and is the headquarters of golf. Abernethy was a Pictish capital. Evidences of Roman occupation exist, and monastic ruins are found in many parts of the "kingdom," as the county is still popularly called. Pop. est. 286,600.

**LITERARY ASSOCIATIONS, ETC.** To Cupar belonged Sir David Lindsay, the 16th century satiric poet, and another of the Lindsays of Fife was Lady Anne Lindsay, who wrote *Auld Robin Grey*. Adam Smith was born at Kirkcaldy, and Balwearie, near by, was the birthplace of Michael Scott the "wizard." At Lower Largo was born Alexander Selkirk, who is immortalised as Defoe's Robinson Crusoe, and is the subject of a poem by William Cowper. Charles I was born at Dunfermline; his sister Elizabeth, queen of Bohemia, at Falkland; Richard Cameron at the same place; Alexander Henderson at Criech; Sir Robert Aytoun at Kinaldie; Thomas Chalmers at

Anstruther; Robert Adam at Kirkcaldy; Sir David Wilkie at Cults. King Alexander III was killed by falling from his horse at Kinghorn. St. Andrews, which is crowded with associations with notable students, has memories of George Buchanan and of John Knox, who began his work as reformer here.

**Fife, EARL AND DUKE OF.** British titles borne by the family of Duff. In 1735 William Duff, who had been M.P. for Banffshire, was made an Irish peer, as Baron Breco. An earldom followed in 1759. James, the 4th earl, was a major-general in the Spanish army during the Peninsular War, and James, the 5th earl, was made a British peer as Baron Skene in 1857. He died in 1879.

His son and successor, Alexander William George Duff, was born Nov. 10, 1849, and was educated at Eton. He sat in the house of commons for the counties of Elgin and Nairn from 1874 until he succeeded to the peerage in 1879. In 1889 he married Louise, eldest daughter of the prince of Wales (Edward VII), and was created duke of Fife, with (1900) special remainder, in default of male issue, to his first and other daughters (by H.R.H. Princess Louise) and their male issue. He died at Assuan Jan. 29, 1912, from a chill contracted at the wreck of the steamer Delhi off Morocco, and was buried Aug. 8, at Braemar.

His daughter Alexandra, who succeeded as duchess of Fife, was born May 17, 1891, and on Oct. 15, 1913, married her cousin, Prince Arthur of Connaught (1883-1938). Their son Alastair Arthur (1914-43) was known by the second Fife title, earl of Macduff, until in 1942 he succeeded

his paternal grandfather as 2nd duke of Connaught. On his death, Maud, younger daughter of the duke of Fife (1893-1945), became heiress to the dukedom of Fife. She married in 1923 Charles Alexander Carnegie (who in 1941 succeeded his father as 11th earl of Southesk), and had a son, b. 1929.

**Fifteen, THE.** Abbreviation for the Jacobite rebellion of 1715, against the Hanoverian dynasty. On Sept. 6 the earl of Mar raised the standard of King James III, the Old Pretender, at Braemar, but the attempt to restore the Stuart dynasty was defeated by Argyll at Sheriffmuir on Nov. 13. See Jacobites; James Edward.

**Fifteenth.** In English history, a tax usually associated with a tenth. Taxation of property other than land began in the time of Henry II, and in 1193 one-fourth of their incomes was demanded from laity and clergy alike. Succeeding taxes of this kind were levied, but the amount varied from a fourth to a fourteenth. Officials from the exchequer arranged for a fixed amount from each shire, leaving it to the sheriff to collect it from individuals. After 1290 it was a vote granted by parliament, each estate voting its own share to the king. Tenths and fifteenths became the regular amount of votes, townsfolk, i.e. the owners of personal property, paying one-tenth of their incomes and those in the country one-fifteenth.

The next charge was to make the amount voted a fixed sum, done by taking the assessment of 1332, which produced £39,000. Henceforward £39,000 represented a tenth and fifteenth, and if more money was needed parliament voted two tenths and fifteenths. In later votes certain towns were sometimes excepted, and the assessment became antiquated and unfair as conditions changed. The last vote of this kind was in 1624; its place being taken by the subsidy (q.v.). See Taxation; Tenth.

**Fifth.** Musical interval. A fifth includes five scale names in order, as C, D, E, F, G. Therefore C to G

is a fifth, and as G occurs in the major scale of C, this fifth is called perfect, or by some major. See Consecutive; Interval.

**Fifth Column.** Name given to any body of persons who work secretly against the established government, used particularly of

those who, during the Second Great War, sought to aid in the subjugation of their homeland by invaders. This phrase was first used during the Spanish civil war, 1936-39, when the Nationalists attacked the Republicans in four columns, while their supporters within Madrid spread alarmist rumours and committed acts of sabotage and espionage. Fifth columnists in Norway,

Fig. Specimen of the tree *Ficus carica* growing in Palestine. On the right are leaves and fruit of the tree, also enlarged flowers male (right) and female

the Netherlands, and N. France gave effective help to the Germans when they launched their campaign of 1940.

**Fifth Monarchy Men.** Sect of the Puritan period in England who believed that a millennium or kingdom of Christ upon the earth was at hand. This was to be the fifth monarchy of the world, the earlier ones being the empires of the Assyrians, the Persians, the Greeks, and the Romans. The Fifth Monarchy Men were to be found in considerable numbers in Cromwell's army. In 1661, shortly after the Restoration, they took part in a revolt in which many were killed.

**Fig** (*Ficus carica*). Tree of the family Moraceae, native of the Mediterranean region. It attains a height of 20 ft. to 30 ft., and has large, lobed, alternate leaves, rough above and downy beneath. The sexes are in separate flowers, but on the same tree. The minute blossoms are contained inside a hollow, pear-shaped flower-stalk. Externally nothing indicates the presence of flowers, and but for the ministrations of a small wasp

(*Blastophaga grossorum*), it would be impossible for the pollen of the males to reach the female flowers. In the same receptacle as the male flowers are some aborted females, and these are attacked by the female wasp, which lays its eggs in them.

The wasp-grubs feed upon their cradles, and in due time become wasps. In seeking the external air they have to pass among the male flowers, and get dusted with their pollen. Then they are attracted by the odours emanating from a cavernous stalk containing female flowers, and enter it, shaking off much of the pollen that covers their bodies; and thus the female flowers are pollinated and the flower-stalks become swollen and juicy. Numerous other species of the genus *Ficus* in other parts of the world bear edible fruit, such as *F. roxburghii* (India), which grows them in clusters from the bare trunk, quite near the ground.

**Figaro.** Central character, the barber himself, in Beaumarchais' comedy, *The Barber of Seville*. Valet, poet, dramatist, etc., he is the personification of the easy gaiety which has come to be accepted as a type of the witty social philosopher. Encouraged by the success of *The Barber of Seville*, 1775, Beaumarchais wrote *The Marriage of Figaro*, which, however, was not acted until 1784, and he also introduced Figaro into *La Mère Coupable*, 1792. Mozart wrote an opera on *The Marriage of Figaro*, and Paisiello and Rossini each wrote one on *The Barber of Seville*. See Beaumarchais.

**Figaro, LE.** Satirical journal founded in Paris in 1826 and named after Beaumarchais' hero. Contributed to by Jules Janin, Alphonse Carr, and George Sand, it ran till 1833. The title was revived for a weekly started by J. H. de Villemessant, 1854. This became a right-wing morning daily devoted to politics and literature in 1866, its writers including About, Hanotaux, Loti, Rostand, and Barrès. Under the control (1901-14) of Gaston Calmette, who was shot by Mme. Caillaux, wife of the French finance minister. March 16, 1914, it enjoyed a great vogue. It published a literary supplement, and a monthly periodical, *Le Figaro Illustré*.

From the German occupation in 1940, *Le Figaro* voluntarily ceased publication rather than

cooperate with the Nazis. After the liberation of France, 1944, it soon reappeared, edited by Pierre Brisson. It trebled its circulation within a year and established itself as a moderate right-wing paper without specific party allegiance.

**Fighter.** An aircraft primarily intended for aerial combat. In the First Great War such aircraft were designated scouts because in the opening phase they were employed largely on reconnaissance; aerial combat had not become a reality. In 1915 these scouting machines were fitted with machine-guns, and their purpose changed; they were no longer observation aircraft but fighters, for their pilots were called upon to seek, engage, and destroy enemy aircraft. The type name was retained, however, until some years after the war ended.

The first scouts (or fighters) were capable of top speeds of only about 65 m.p.h., but by the end of 1916 British, French, and German machines were flying at over 100 m.p.h. Engine power rose from 80 h.p. to 200 h.p., and by 1918 some fighter aircraft went into action with four machine-guns installed. With few exceptions all these aircraft were biplanes. The general use of metal in the construction of fighter aircraft in the post-war years was followed by development of the monoplane type.

#### Increase in Engine Power

At the outbreak of the Second Great War British and German fighters were equipped with engines of more than 1,000 h.p. The essential requirements of all fighter aircraft were and remained abundant engine power, high speed, and formidable armament. Through increasing the h.p. of the engines used in 1939 from 1,030 to more than 2,000 in 1945, the fighter speeds rose from about 340 m.p.h. to more than 460 m.p.h. The machine-gun was gradually replaced by cannon and rocket projectiles. To enable the aircraft to operate at altitudes of 40,000–50,000 feet, special superchargers and special airscrews were introduced. The cockpits were sealed and pressurised to make it possible for the pilot to breathe at such altitudes. Petrol tanks could be dropped from the aircraft when the additional fuel they contained had been expended. The most important change in fighter design introduced during the war was the use of the gas turbine-driven compressor units producing jet propulsion. The R.A.F. and the Luftwaffe employed such

aircraft operationally in the last phase of the conflict, speeds of more than 500 m.p.h. being attained.

Closely related to the true fighter were the fighter-bomber and the night fighter. The former was a variant of the normal fighter. It carried bombs weighing up to 1,000 lb. on external bomb racks, and when so loaded was employed in low level attacks on small targets, either moving or static. For the night fighter, the primary task was engagement with enemy bombers. Its essential qualities were long range, speed, and powerful armament. Whereas the ordinary fighter aircraft was a single-seat machine, the night fighter usually carried a pilot and a navigator. Naval fighting aircraft, flown from the decks of aircraft carriers, were also extensively developed during the Second Great War. Arrestor gear and folding wings were included in their design. See *Hurricane*; *Messerschmitt*; *Spitfire*, etc.

**Fighter Command.** Operational command of the Royal Air Force responsible for the interception and destruction of enemy aircraft, the escort of bombers, the carrying out of offensive sweeps and patrols, and, in conjunction with Coastal Command, the protection of shipping. Fighter Command evolved from the squadron of reconnaissance, artillery spotting, and photographic survey aircraft which in 1912 formed the nucleus of the Royal Flying Corps. The machines were totally unfit for fighting and little was known about the implications of aerial combat. The only armament consisted of revolvers or rifles carried by pilots and observers.

In the early months of the First Great War, pistols, rifles, small grenades, and incendiary bombs were the sole armament of military aircraft. The scout aircraft performed the elementary functions of a fighter and air fighting tactics consisted in getting above an enemy aircraft and attempting to drop an incendiary bomb on top of it. Early in 1915 the Germans began to make armed reconnaissance flights and bombing raids over the British lines. To combat this new development of air warfare, a number of Bristol and Martinsyde scout aircraft were fitted with machine-guns on the side of the fuselage and set at an angle to clear the airscrew. Somewhat later, machine-guns were fixed to fire through the propeller, being actuated by a synchronising

gear. By 1918, fighter tactics became highly developed, but with one or two exceptions similar types of aircraft were used for both fighting and bombing.

After 1918, the development of aircraft with great range and heavy load capacity led to the evolution of aeroplanes designed for the specific purpose of bombing. To combat the bomber, designers concentrated upon the production of a high speed aircraft with a rapid rate of climb and sufficiently sturdy to carry eight machine-guns. This led to the evolution of the fighter pure and simple, and the establishment, July 14, 1936, of Fighter Command to develop and exploit the tactics of air fighting. The command was divided into groups, which were subdivided into wings, themselves consisting of several squadrons. The squadrons were stationed at aerodromes controlled by their appropriate groups and equipped with day or night fighters or fighter-bombers, according to the particular operational duties of the wing. Fighter Command coordinated not only the operations of the fighter squadrons, but of all other weapons used against hostile aircraft. It issued the orders and warnings which set the air defence system in motion.

#### Radio-Telephony Control

**Aerodromes under Fighter Command** were ranged in sectors, a specified number of sectors being controlled by one of the groups, and the groups themselves being under Command H.Q. An elaborate system of communications controlled the whole, and each sector controlled by radio-telephony the movements of all fighter aircraft in the air. Operations rooms at sector, group, and H.Q. plotted all information about hostile aircraft, and at Command H.Q. provided a picture of the entire air battle front. On all operational stations in wartime a squadron of fighters was kept at three-minute readiness to take the air upon receipt of orders from the controller.

Squadrons from Fighter Command accompanied the B.E.F. to France in Sept., 1939, but in the first months of war their activities were mainly confined to armed reconnaissance and the protection of aircraft engaged in aerial photography. With the German invasion of Norway, France, and the Netherlands, Fighter Command was called upon to take up its true rôle; but necessarily retained the bulk of its squadrons in Great Britain to repel anticipated

bombing raids. Its work was restricted to operations designed to delay the advancing enemy and cover the evacuations from Norway and Dunkirk.

Following the defeat of France, Fighter Command disposed its resources for the coming battle of Britain (*q.v.*). No. 11 group, protecting London, the Thames estuary, and S.E. England as far as Portsmouth and East Anglia, bore the brunt of the fighting. No. 10 group protected southern England W. of Portsmouth and also South Wales; No. 12 group the Midlands and east coast from Great Yarmouth to Scarborough. No. 13 group was responsible for the Tyne, Tees, Forth, and Clyde areas and the Scottish east coast. Squadrons from No. 13 had been the first units of Fighter Command to go into action over Britain, when they attacked the German bombers raiding the Firth of Forth on Oct. 16, 1939.

In July, 1940, immediately before the battle of Britain opened, Fighter Command had a front line strength of 640 aircraft, Hurricanes and Spitfires with a few Defiants. Against them the Luftwaffe was able to dispose 1,200 long-range bombers, 1,100 twin- and single-engine fighters, and 350 dive-bombers operating from aerodromes set in a great crescent from Amsterdam to Brest. During the battle of Britain, Fighter Command had the major share in destroying 1,733 German bombers. The command lost 375 pilots killed and 358 wounded in the battle.

#### Offensive Fighter Sweeps

With the decline of the raids on Great Britain, squadrons of Spitfires and Hurricanes were detailed by Fighter Command to sweep over N. France as escorts to groups of day bombers. The first all-fighter sweep was made Jan. 10, 1941, when 100 Hurricanes flew over the Pas de Calais, attacking enemy aerodromes and road and rail transport. On subsequent occasions 1,000 fighters a day were often engaged in such sweeps.

In Jan. also Fighter Command introduced intruder patrols. These consisted of night sorties over enemy territory for the purpose of shooting down German aircraft over their bases as they took off or returned from raids over Great Britain. Somewhat later the command put into service fighter-

bombers, dropping an average of 135,000 tons of bombs a year. Another development was the night fighter. In conjunction with the Fleet Air Arm, the command also provided pilots and aircraft for the fighters catapulted from merchant ships.

On Nov. 15, 1943, the command was temporarily suspended, defensive fighters being incorporated into a new command known as Air Defence of Great Britain. The fighters squadrons engaged in sweeps and those working in close support of the army were embodied in what was known as tactical air force (*q.v.*). But Fighter Command was reformed on Oct. 15, 1944. Throughout the Second Great War, the command lost 3,558 aircraft and suffered 12,481 casualties, of which 3,143 were pilots killed on operational sorties. See Air Defence of Great Britain; Air Fighting; Fighter; Royal Air Force.

**Fighting Fish.** *David Le Roi* Name given to various species of small fresh-water fish, *e.g.* *Betta pugnax*, found in Asia and Africa. The Siamese breed it for contests, as it fights furiously when matched with an opponent. It assumes vivid hues when excited.

Fighting Fish. Specimen of the Japanese *Betta splendens*

**Fighting France** (*La France Combattante*). Title adopted on July 14, 1942, by Free France (*q.v.*). The French National Committee (*q.v.*) felt Fighting France to be a more exact definition of the Free French movement, since it linked Frenchmen fighting outside France with those resisting the Germans inside the country. The French National Committee and the British government agreed that Fighting France was the symbol of resistance to the Axis (*q.v.*) by all French nationals, wherever they might be, who repudiated the capitulation of June, 1940, and that the French National Committee was the directing organ of Fighting France. See France in the Second Great War.

**Fighting Top.** In ancient naval warfare, a platform or large barrel high up on the mast from which heavy weights could be thrown into any vessel lying alongside, either to disable men or to drive a hole through the bottom of the ship. Later on, fighting tops were occupied by archers and riflemen; in sailing ships they were represented by the "tops," or platforms built at the head of the

lower masts, where picked marksmen were stationed during close-fought actions. From the mizen-top, the platform on the after-mast, of the Redoubtable the shot was fired that killed Nelson.

In the later years of the pre-Dreadnought era fighting tops were equipped with machine and light quick-firing guns for driving off hostile torpedo-craft, but as the size of the latter and the range of torpedoes increased, it became impossible to mount in these positions guns sufficiently heavy and far-reaching for the purpose. Warships continued to have large structures built high up on the masts, but these were occupied in action by the spotting officers and apparatus connected with fire-control. On some warships the foremast and fighting top were replaced by an armoured control tower, from which the main armament was ranged and fired. This tower was known as the citadel. See Battleship.

**Fig.** Walled oasis of Morocco, on the borders of Algeria. It lies 3 m. N.E. of Beni Unif, and 165 m. E.S.E. of Fez, and is a station on the rly. from Oran to Colomb Béchar. There are 250,000 date palms and a considerable trade is carried on with Morocco. The inhabitants belong to the Amour tribe. After a revolt in 1903, order was established by a French military mission. Alt. 2,700 ft.

**Figl, LEOPOLD** (b. 1902). Austrian politician. Born in Upper Austria, he studied agricultural engineering in Vienna and became an active member of the Clerical party led by Seipel, Dollfuss, and Schuschnigg. He was interned by the Nazis soon after their annexation of Austria in 1938, and spent some six years in Dachau concentration camp. Liberated in 1945, he reconstructed the R.C. or People's party, which at the general election of Nov., 1945, secured 51 p.c. of the seats. Figl was chosen chancellor of Austria, while the provisional holder of that office, the Socialist Karl Renner, became president.

**Figline.** Town of Italy, in the prov. of Florence. It stands on the river Arno, 15 m. by rly. S.E. of Florence. It manufactures wine and cutlery, and straw-plaiting is carried on. In the vicinity is Monte Ferrato (alt. 1,385 ft.), noted for its quarries of serpentine. *Pron.* Fil-yeeny.

**Fig Marigolds** (*Mesembryanthemum*). Large genus of fleshy herbs and sub-shrubs. Belonging to the family Ficoidae, they are

natives of hot, dry climates, especially S. Africa. The leaves vary greatly in the different species; the flowers are large and conspicuous, white, yellow or red, with many long, slender petals. See Ice-plant.

**Figueira**, GUILLEN (c. 1190-1250). One of the later Provençal troubadours. He was born at Toulouse, and is reported to have been a tailor. When the persecution of the Albigenses took place he wrote vigorously in their defence, and on the persecutors' capture of Toulouse took refuge in Italy. In the struggle between the Empire and Rome he sided with the former, and one of his *serventes* is a denunciation of the latter. He also composed some notable love songs. *Pron.* Feegay-eera.

**Figueras**. Town of Spain, in the prov. of Gerona. It stands in a fertile plain near the French frontier, 27 m. N.E. of Gerona on the Barcelona-Perpignan rly. The town is strongly fortified, with a citadel built by Ferdinand VI, which is considered a key to the frontier. There is important trade in soap, wine, leather, cork, and textiles. The town fell three times to the French—in 1794, 1808, and 1823. At the close of the civil war of 1936-39, following the fall of Barcelona, Jan. 26, 1939, the Spanish Republican government fled to Figueras, but the town was captured by Franco's forces on

Feb. 8, after a heavy toll of civilian life through bombardment. The last meeting of the Cortes was held here on Feb. 3, only 62 deputies being present out of 473. Pop. 15,680. *Pron.* Feegay-rahss.

**Figueras y Moracas**, ESTANISLAO (1819-82). Spanish statesman. Born at Barcelona, Nov. 13, 1819, he studied law. As a republican he was elected to the Cortes in 1851. Prominent in the revolution of 1868, he strongly opposed all attempts to restore the monarchy, and upon the establishment of the republic of 1873 became president of the provincial council of ministers. He occupied a prominent position in politics until 1874, when the restoration drove him into retirement. He died at Madrid, Nov. 11, 1882.

**Figurate Number**. Term used in mathematics. In an arithmetical progression, if the first number is a unit and the successive numbers differ from it by whole numbers, as in such a series as 1, 2, 3, 4, 5, then a new series may be formed by adding together the first two terms, then the first three terms, then the first four terms, etc. The new series would thus be 1, 3, 6, 10, 15. These numbers are called figurate numbers. Similarly another series, 1, 4, 10, 20, 35, etc., might be formed from the second series.

**Figured Bass**. In music, a bass part provided with figures to indi-

cate the chords which should be added to it. See *Basso Continuo*.

**Figure-Head**. Image painted or carved on the prow of a war vessel. It doubtless originated in the sentiment that a ship was a living thing and should be given in at least one respect the external appearance of one. Possibly, too, the ferocious aspect of a grotesquely shaped animal in the bows had some sort of moral effect upon ancient or uncivilized warriors.

In the days of the oared galley the figure-head was made to fill the purpose of an above-water ram. Projecting further in advance of the bow than the ram below water, it was driven with such force against an enemy's side as to cause the vessel to heel over, thus giving the submerged projection the opportunity of striking in a more vulnerable and vital part of the hull. When the sail superseded the oar as a means of propulsion, the figure-head ceased to have any practical value, but it was retained for ornament, and as an expression of sentiment. The Royal Sovereign, completed in 1880, was the last warship built for the Royal Navy to have a figure-head. In 1904 the *Swiftsure* and *Triumph*, built for Chile, were taken over by the Royal Navy, and both these vessels had bow scrolls. Many figure-heads of old British warships are to be seen in naval museums.

Figure-Heads in the Royal Navy. 1. Marlborough, old three-decker wooden sailing ship now in Portsmouth harbour. 2. Minotaur, ironclad cruiser built in 1863. 3. Duke of Wellington, built in 1852. 4. Warrior, the first ironclad, launched in 1860. 5. Iris, steam and sail ironclad built in 1877. 6. Figure-head intended for Royal Frederick, 1841.

Photos 1, 2 and 5, H. Symonds & Co., Portsmouth, 3, 4 and 6, Cribb, Southsea

**Figwort** (*Scrophularia*). Large genus of herbs, of the family Scrophulariaceae. They are natives of Europe, Asia, N. Africa, and America. They have tuberous or creeping rootstocks, opposite leaves, and somewhat globular flowers of a greenish-purple or yellow hue, succeeded by a two-valved capsule. As a rule they have an unpleasant odour. *S. nodosa*,

Figwort. Leaves and flowers of the knotted figwort

the knotted figwort, is used by farmers to make a decoction for the cure of scab in swine.

**Fiji or Viti Islands.** Crown colony of the British Empire. It consists of a group of nearly 250 islands and islets in the S. Pacific Ocean, lying mostly between lat. 15° and 20° S., and long. 175° E. and 178° W. The total land area, including Rotuma, is 7,083 sq. m. About 80 islands are inhabited, but only three are large: Viti Levu (area 4,053 sq. m.), Vanua Levu (2,130 sq. m.), and Taviuni (217 sq. m.); smaller islands are Ovalau, Kandavu, Ngau, Koro, and Rotuma. The remainder are islets and atolls, bounded by reefs.

The islands are of volcanic origin, but beyond a few thermal springs there are no signs of recent activity. The larger islands are mountainous, rising to 4,000–5,000 ft., densely forested in parts (2,366,000 acres under forest), abounding in valuable woods, but the sandalwood for which the Fijis were formerly noted is almost exhausted. There are many good harbours and a few navigable rivers. The climate is healthy and agreeable, the rainfall plentiful; the mean temperature is about 70°, and malaria is rare. The islands are subject to hurricanes between Dec. and

April. The soil is extremely fertile, the chief products being coconuts, sugar, cacao, yams, bananas, maize, rice, tobacco, rubber, and turmeric. Horses, asses, cattle, sheep, pigs, and goats are reared.

The chief exports include sugar, copra, molasses, cotton, rubber, green fruit, and sici shell. Steamer

communication is normally maintained with Australia, New Zealand, Honolulu, Canada, Tonga, and Samoa. About two-thirds of the trade is done with British possessions. There are seven wireless telegraphy stations, and cable communication with Aus-

Fiji. Fijian girl. Right, native man of Malayan-Polynesian origin

tralia, New Zealand, and Canada. There are 384 schools, 23 being under government control. Religion is mainly Methodist and R.C. Money, weights, and measures are as in Great Britain. The capital is Suva (pop. 11,398) on the S. coast of Viti Levu.

The Fiji Islands were discovered by Tasman in 1643; visited by Cook in 1769; ceded by the ruling chiefs to the British Empire, Oct. 10, 1874. Under the constitutional arrangement of 1937 they are administered by a governor appointed by the crown, who

Fiji. Map of the South Pacific islands ceded to Great Britain in 1874

is assisted by executive and legislative councils. A fair amount of self-government is allowed; local administrative units called *tikina* are under native chiefs. The governor is high commissioner and consul-general for the West Pacific. After the entry of Japan into the Second Great War in Dec., 1941, a Fiji defence force was formed. Fijian units served on Bougainville and in other operations in the S.W. Pacific. The islands were used by U.S. troops as a training ground in tropical warfare. They gave more than £52,000 to the Imperial govt. towards the war. Pop., est., 240,641: Fijians, 111,346; Indians, 109,488; Europeans, 5,245;

Chinese, 2,351; Melanesians, Polynesians, Rotumans.

**Filament.** A high resistance tungsten wire in an electric lamp which becomes incandescent when current passes through it. In ordinary lamps the wire is wound in a close coil. In "coiled coil" lamps the coiled filament is again coiled on itself, giving a concentrated light source of high efficiency.

Fiji arms

**Filament Lamp.** Before 1878 the arc lamp had the electric lighting field virtually to itself. This form of lighting, however, was available only in inconveniently large units, and the problem of "subdividing the electric light" was urgent. The obvious method was to develop heat in a filament; but whereas existing conductors could produce a great deal of heat without destroying themselves, they could not emit an economic amount of light. In 1845 Staite, an arc lamp engineer, exhibited a lamp with a platinum-iridium filament in a vacuum, but found that the metal was rapidly dissipated by evaporation at a temperature that did not give rise to a useful amount of light.

The curves in Fig. 1 illustrate the temperature requirements of a filament, showing the relative amount of energy radiated at the various wavelengths at four fixed temperatures. Since the only visible radiation is that between 0.4-0.7 microns, the small areas left shaded are alone useful for lighting purposes. Thus at 1,000° C. no light is given at all; at 2,000° C. only a small fraction of the total energy is useful; but further temperature rise causes a valuable increase in efficiency.

It was therefore necessary to find the material and the conditions of running that would permit the highest temperature to be maintained for a reasonable "life"; and 1,000 hrs. has always been regarded as the standard value for the latter. The chief requirement is evidently a high melting point; but all materials evaporate rapidly at temperatures well below this. The conductor with the highest melting point then known was carbon (3,500° C. as compared with 1,764° C. for platinum). Swan, who had seen Staite's demonstration,

constructed a number of carbon-filament lamps from 1855, but no practical commercial model

Filament Lamp. 2. Swan's carbon-filament Lamp of 1878

till 1878 (Fig. 2). This lamp had a thin vertical rod of hard carbon, but about two years later he improved on this with a filament of cellulose drawn through a diamond die and carbonised. Finally in 1884-85 he developed the "squirt- ing" process, which became the standard method of filament making everywhere.

Filament Lamp. Metal filaments: 3. Cage filament for vacuum lamps; 4. Wreath filament for small gas-filled lamps; 5. Festoon filament for large gas-filled lamps; 6a. Coiled-coil filament, greatly magnified; 6b. Comparison between coiled-coil, and coiled filaments, showing layer of inert gas around each

Carbon possesses the disadvantage of evaporating at a relatively low temperature, but it was not till 1898 that a better material was found, in the rare metal osmium, by Welsbach in Germany. This was followed by tantalum in 1903, but in 1904, before the latter could become established, the tungsten filament (m.p. 3370° C.) was developed in America. At first it was "squirted" in the form of a metal powder mixed with a binder and then calcined or sintered, but Lang-

muir in 1906 discovered the process for wire-drawing the metal at a high temperature. The wire was wound between two molybdenum "spiders" in "cage" form (Fig. 3), and run in a vacuum of about 10<sup>-4</sup> mm. of mercury. Its efficiency had reached about four times that of the carbon lamp.

In 1913 evaporation was reduced by replacing the vacuum with a filling of inert gas, argon mixed with about 10 p.c. of nitrogen being found the most effective. To minimise convection loss, it was now necessary to concentrate the filament, by making it in the form of a closely wound spiral, which was supported as a horizontal wreath for the smaller lamps (Fig. 4), or festooned in a series of Vs (Fig. 5) for the larger. A whiter light was the result, with an efficiency about seven times that of the carbon lamp. A further improve-

ment was effected in 1936, by coiling the already coiled filament, as shown in Fig. 6a. This added a further 20 p.c. to the light output, making it about eight times that of the carbon lamp.

Filament lamps should be run at their correct voltage. If this is exceeded by 10 p.c., 38 p.c. more light is given, but the life falls to 300 hrs. instead of 1,000. Lamps for projection purposes are designed to run at about this intensity.

**Filangieri, GAETANO** (1752-88). Italian lawyer. The son of Caesar Filangieri, prince of Arianiello, he was born at Naples, Aug. 18, 1752, and became a lawyer. He is chiefly known for his work, *The Science of Legislation*, which secured a

Filament Lamp. 1. Relative amounts of energy emitted by filament at various wavelengths in microns for 5 different temperatures. Energy used as visible light up to 2000° C. is shaded (see text)

European reputation. This is unfinished, only four out of its six books being completed; it deals with legislation, economics, and education, and shows its author as a thinker much in advance of his time. Filangieri passed much of his life in Spain, where he held appointments at court, and died at Vico Equense, July 21, 1788. The Science of Legislation was translated into English by Sir R. Clayton, 1806.

Filangieri had a son, Carlo (1784-1867), famous as a soldier in the French service. He began his career under Napoleon and saw service at Ulm, Austerlitz, and elsewhere. His name is chiefly associated with Sicily; in 1848 he was sent there by Ferdinand II, king of Naples, to subdue the rebels, and he remained in the island as governor until 1855. In 1859 he was made prime minister by Francis II, king of Naples, but he soon resigned because his suggestions for a more liberal form of government were rejected. Made prince of Satriano, he died Oct. 9, 1867.

**Filaria** (Lat. *filum*, thread). Genus of Nematode or threadlike worms, many of which are parasitic in the bodies of man and other animals. Certain of these minute worms are the cause of various diseases, most of them peculiar to tropical countries. *Filaria bancrofti* lives in its adult stage in the lymphatic glands, while its embryos, *Microfilaria sanguinis-hominis*, are found in the blood.

File. Left, double-cut rough file; centre, single-cut rough file; right, horse rasp, showing burrs

It is conveyed by the bite of a mosquito, and is the cause of elephantiasis and haematuria. Pathological changes are due partly to mechanical blockage of the lymphatics, and partly to toxins elaborated by the worms and to secondary invasion by streptococci. *Filaria medinensis* is known as the guinea worm, and encysts under the skin of the back and legs, forming subcutaneous abscesses. The larval stage is passed in the cyclops, and the larvae probably conveyed to man by impure drinking water. See Tropical Diseases.

**Filariasis.** Disease caused by infection with a nematode worm belonging to the family Filariidae. Several genera and species are

recognized, but by far the most important is the *Filaria bancrofti*. See Elephantiasis.

**Filbert.** Fruit of the cultivated hazel. In it the leathery husk is greatly extended so as to conceal the nut. Its proper name is Philibert nut, so called from S. Philibert, whose day is kept Aug. 22 during the height of the nutting season. See Hazel.

**Fildes, Sir Luke** (1844-1927). British artist. Born at Liverpool, he studied at Chester, Warrington, South Kensington, and the Academy schools. He began his career with black and white work for The Graphic, contributing a sketch of Casuals for the first number, 1869; this was, in 1874, the subject of a popular picture at the R.A. He illustrated Dickens's Edwin Drood in 1870. The Doctor, 1892 (Tate Gallery), set the seal on Fildes's reputation as a painter of sentimentally pathetic subject pictures. In 1901 he painted the official portrait of Edward VII, and in 1905 that of Queen Alexandra. He was elected A.R.A. in 1879 and R.A. in 1887, and knighted in 1906. He died Feb. 27, 1927.

*Luke Fildes*  
Russell

**File.** Hand tool used for shaping and smoothing metal. Files are also used to sharpen saws. Many varieties are used: flat, taper, round, square, three-square or triangular, half-round, and rat-tail or tapered round. In flat files both faces

and edges may be cut; if one edge is left smooth the file is said to have one "safe-edge." The best files are made of the finest crucible cast steel; the cutting edges are formed by means of a short chisel, held at an angle on the "blank," as the uncut shape is called, and struck with a hammer. A rasp is a file in which a series of strong burrs are made by a pointed punch.

Standard files are single cut or double cut. The cutting begins at the point of the file and advances by steps according to the intended fineness of the file. After the first cutting is finished, if the file is to be double cut, it is gone over again with the chisel held so as to cross the former cuts at an angle. Cutting surfaces of files are distinguished in a complete series as rough, middle cut, bastard, second cut, smooth, and dead smooth. The sizes range from a watchmaker's tool, about three-quarters of an inch long, to files three feet in length. "Swiss" files of superhard steel have long held the field for jewellers' and watchmakers' work, making precision instruments, etc. Most files are provided with a "tang," a pointed end intended to be driven into a wooden handle. Files are cut while the blanks are in the soft or annealed state, and are afterwards hardened, great care being taken to avoid distortion of their shapes. Skill in filing, the ability to file a surface flat, is still the hall-mark of a good mechanic; though machine tools have somewhat diminished the importance of the art.

**File** (Lat. *filum*, thread). Military term for soldiers formed up behind one another. In the British army men fall in in three lines; those abreast form the ranks; each man in the front rank with the men immediately behind him forms a file. When numbered off, the front rank man numbers for his file. If the total of the men in the squad is not divisible by three, the last file but one, known as the blank file, has only one or two men.

**File Fish.** Member of the genus *Balistes* of the order *Plectognathi*, an order of sea fish.

**Filey.** Urban dist. and seaside resort of the East Riding of Yorkshire, England. It is 7½ m. S.E. of Scarborough on the railway, and is pleasantly situated on the cliffs

Filey. Filey Brigg, principal feature of the coast at this Yorkshire holiday resort

By courtesy of British Railways

overlooking Filey Bay. It possesses a fine stretch of firm sand, a good promenade, and golf links. Here is also situated a large permanent holiday camp. Filey Brigg, on the N. part of the bay, is a ridge of sandstone stretching  $\frac{1}{2}$  m. out to sea. S. Oswald's, a cruciform building, partly of Norman work, partly Early English, is the chief church. Until recently the boundary between the E. and N. Ridings of Yorkshire separated this church from the town proper. A gunnery school and infantry training centre were established for the R.A.F. Regiment at Filey during the Second Great War. Pop. 4,000.

**Filibranchiata.** An Order of molluscs belonging to the Lamellibranchiata, often called the bivalves. Members of this order have filamentous gills.

**Filibuster.** Term, probably of Dutch origin, originally applied to the buccaneers or 17th century pirates infesting the Spanish-American coasts and later to the irregular adventurers who organized expeditions in Spanish-American revolutions; e.g. Lopez against Cuba (1850-51), Walker against Nicaragua (1855-60). Metaphorically it denotes a member of an American legislature who attempts, either singly or as one of a group, by means of tactics permitted under its rules of procedure, to prevent or delay the passing of a resolution approved by the majority. In the U.S. senate in 1908 Senator La Follette spoke continuously for 18 hours against a currency bill, and in 1935 Senator Huey Long for 16 hours against the extension of the National Industrial Recovery Act.

**Filigree** (Lat. *filum*, thread; *granum*, grain). Form of decorative work carried out with fine wire of gold, silver, or copper. It has been used for jewelry and ornament from prehistoric times, sometimes alone, sometimes in combination with solid metal, enamel, and precious stones. The Etruscans and later the Byzantines combined filigree work with granulation—a type of decoration consisting of small and large balls. In early work the dainty wire patterns were attached to metal plates, and when the space between was filled with enamel it was known as filigree enamel. Treatment varies a good deal. Indian work is mostly floral, very thin wire filling in the space between the outline of thicker flattened wire. Maltese filigree is like cobwebby lace, as is much from Portugal.

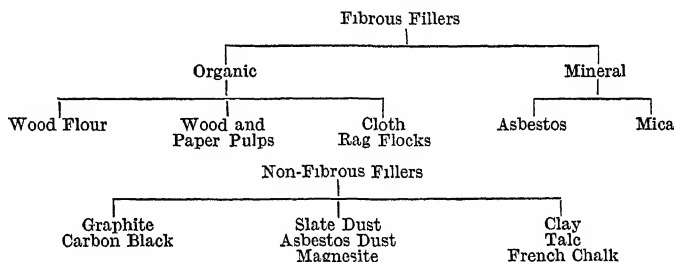

Apart from its use for articles for personal adornment, filigree decoration was used in medieval times to embellish reliquaries, and, from this, detached lacework in Gothic architecture is sometimes called filigree work. (See Byzantine Art, illus. p. 1607.)

There are two types of filigree glass: (1) interwoven or spirally twisted clouded or coloured threads embedded in the glass; (2) surface decorations or other ornaments carried out in glass threads.

**Filipinos.** Name applied generally to the native inhabitants of

**Filler.** A word used in several senses, e.g., a vessel for filling others; a man who fills barrows or trucks with excavated material in preparing ground for building and civil engineering works; and especially any packed material surrounded by wrapping.

More important is the use of the word to include fillers or extenders used in manufacturing processes to impart strength, durability, resistance to abrasion, good electrical properties, etc. The table shows a useful classification of fillers of this kind.

the Philippine Islands (*q.v.*). They belong to tribes of Malayan stock. The Liga Filipina was founded about 1890 by Dr. José Rizal (*q.v.*) with the object of securing more freedom for the inhabitants than they then had under Spanish rule, and subsequently the term Filipino came into general use.

**Fillan** (d. c. 777). Scottish saint. According to the Aberdeen breviary, he was the son of S. Kentigern, and early in life became a monk. He lived for some years in a cell near St. Andrews, where he was later elected abbot. He retired to Glendochart in Perthshire, where he founded a church. He was buried at Strathfillan. His festival is on Jan. 9.

Most of these fillers are found useful in the manufacture of paper, plastics, paints, hard rubber, etc.

Barytes, chalk, china clay, gypsum, talc, silica, and slate dust are used as fillers in paint, not solely for the purpose of cheapening it but to improve its general qualities, notably durability. In paper-making, loading with such fillers as barytes, whiting, or titanium oxide, assists the production of a high degree of whiteness and opacity.

In the rubber industry (e.g. rubber tires), zinc oxide, carbon black, lamp black, and occasionally whiting and fossil meal increase durability, resilience, and resistance to weathering.

Synthetic resins and plastics, particularly of the bakelite type, mixed with such fillers as asbestos fibre, cotton flocks, wood flour, and mica, yield a powder which can be filled into the moulds of heated presses. Under the influence of heat and pressure the resin liquefies and, with the filler, bonds into an infusible form with great mechanical strength, good electrical properties, resistance to heat and temperature changes, and unaffected by moisture and solvents.

Vulcanised rubber for the electrical industries may be compounded with mineral fillers according to requirements. Powdered cork in linoleum; whiting and powdered graphite in solid lubricants; and mineral sub-

Filigree. Gold necklace of sixteenth century Venetian work

stances for loading certain textiles are other instances of the use of fillers.

H. M. Langton

**Fillet** (Old Fr. *fillet*, little thread). Term in architecture, signifying a narrow moulding or flat band in a moulding. It is also used to indicate the flat ridge between the flutes of a shaft. *See* Fluting; Moulding.

**Fillmore, MILLARD** (1800-74). President of the U.S.A. Born Feb. 7, 1800, in New York state, the son of a settler, he had a rough boyhood. Apprenticed to the cloth trade, he began to study law, and earned a livelihood by teaching at Buffalo until qualified to practise. This he did at Aurora, where he was soon the head of a prosperous firm. In 1829 he entered the legislature of New York. In congress he sat as a Whig, 1833-35 and 1837-43, becoming a prominent speaker in the house of representatives. In 1848 he was chosen vice-president, and on July 9, 1850, on Taylor's death, he succeeded to the presidency.

On the slavery question Fillmore was a moderate. On the one side he pressed forward in 1850 the fugitive slave law and other measures of compromise; on the other he had supported legislation for preventing the extension of slavery outside the existing slave states. But the Whigs declined to put Fillmore forward again; when he stood for president, 1852, only one state supported him; and his term ended March 4, 1853. He died at Buffalo, March 8, 1874.

**Film.** A flexible material used in photography in place of glass plates as the support of the sensitive emulsion in the making of negatives. The advantages of film are reduction of weight and the facility of loading the camera and developing the negatives without a dark room, and non-liability of the negatives to breakage when stored. Celluloid was formerly almost exclusively used as flexible support, but has now been largely replaced by an acetate base which is non-inflammable. Paper is employed in some recording instruments such as oscillographs and cardiographs. The sensitive film is generally used as a long band backed with a longer band of black paper, wound together as a spool or bobbin. The extra length of paper at each end allows of the spool's being inserted in one chamber of a film camera, and then of the film's being wound on to a second but empty spool after exposure. Owing to the enveloping black

paper both operations can be done in full daylight, and material for any number of photographic subjects can thus be carried and used without a dark room. In the miniature film cameras using 35-mm. perforated film, the paper backing is dispensed with, the film being loaded into a light-tight cassette which is inserted in the camera from which it passes into a similar holder or is rewound into the original cassette before removal from the camera. A limited use of unbacked film is also made in other sizes of specially designed cameras. The so-called "daylight loading" of film cameras was introduced commercially in 1891 by the Eastman Kodak Co. for the Eastman roll-film introduced in 1889. Emulsion-coated film of stiffer substance is also used in cut pieces, and is handled in the same way as dry plates.

**FILM PACK.** This is a carton of cut films placed one behind the

other, each with a protruding paper tab attached and so arranged that by drawing out the appropriate tab the film which has been exposed is drawn round to the back, leaving the next film in position for exposure. The film pack is a daylight loading device and is placed in the camera in a special adaptor which replaces the usual dark slide. A film strip is a strip of perforated film 35 mm. wide of the type marked as safety, carrying a series of photographic images adapted for optical but not for cinematographic projection. It is not bound between glass or other protective medium. The usual size of each frame is 36 mm. long by 24 mm. wide. The film strip has largely replaced sets of lantern slides for educative and instructional purposes. A film strip projector is an optical lantern, automatic or semi-automatic in action, specially designed for the projection of film strips.

## FILM: A 20TH-CENTURY ART FORM

*This article examines the varied types of entertainment and information which moving pictures provide. For the scientific, technical, historical, administrative, and legal aspects of the industry, see Cinematography*

In the cinematograph trade the word film is generally used in the U.K. not only for the photographic film itself but for the sequence of pictures as projected from that film on the screen, being thus analogous with a play or a novel, and therefore suitable for consideration as a work of art. The corresponding American term is motion picture or "movie."

The earliest cinematograph films, in the late 1890s, were content with the wonder of recording mere incidents of movement of the "train coming into a station" kind. These simple experiments were the historical basis of a highly developed art, the later additions of sound and colour having only enlarged the scope of the same art, the essence of which is to awaken particular impressions and responses by the creation of an illusion of reality within its own conventions, the chief means of illusion still being movement.

The simplest form is seen in the news film, which was originated as early as 1896 with a film of the Derby shown in London on the evening of Derby day. Most cinemas include in their programme a series of brief topical films, a spoken commentary usually supplementing such sounds as were actually recorded with the taking of the pictures. The items

filmed are almost always pre-arranged public events and sporting occasions. Only rarely is a film camera fortunate enough to pick up an unexpected item of news, though this has sometimes happened either through intelligent anticipation or through luck, as in the filming of the 1913 Derby when a camera at Tattenham Corner recorded the tragic incident of Emily Davison throwing herself in front of the King's horse, or when the screen was able to show clearly that a goal in the 1932 F.A. Cup final was kicked from the wrong side of the line.

Closely allied to the news films are the topical feature films, including fashion displays and personal interviews, and the so-called "travel" films, which are in effect conducted tours in unfamiliar parts of the world. The latter were first popularised during the opening decade of the 20th century by such enterprises as Hale's Tours of the World. Travel films, like nature films, form a considerable proportion of those designed primarily for educational purposes, which also include those which illustrate by the aid of animated diagrams various branches of science.

A variation of the informative feature film is seen in the American series, *The March of Time*, which,

beginning in 1935, led the way in the judicious selection of factual camera shots to give point and purpose to a single topical theme. A more considered exploiting of this device is presented by the "documentary" films, as developed by John Grierson and other British directors. These records of life and industry are based on factual material but aim at an imaginative interpretation of the subject. They can focus on high lights and striking contrasts, and may reveal an underlying rhythm to which the music and spoken commentary of the sound track give emphasis.

#### Tricks and Devices

In a class by themselves are what were once known as trick films, using to the full the camera's power of illusion in startling or amusing ways, e.g. by double exposure, backward projection, ultra-slow or ultra-rapid exposure. Though the trick film as such has become a rarity, its devices have been fully employed in other types of films, from the "slow-motion" informative film revealing the full grace of athletic movement and the "rapid motion" educational film (e.g. showing the growth of flowers) to the use of illusory effects in fantastic films like *The Invisible Man*, *Blithe Spirit*, or *A Matter of Life and Death*. Very early films of this type were made by a French director, Méliès, e.g. *A Trip to the Moon* (1902). Other often-used devices, or tricks, include the superimposing of background scenery, the use of small scale models, and the "doubling" of a star actor's part for the more violent kind of incident; also such methods of switching from one scene to another as the "fade," the "dissolve," and the "wipe," terms which explain themselves.

The trick film was also the parent of the animated cartoon, which brings drawings to life. Cartoons date from 1908, when Cohl made his *Phantasmagoria*. Their popularity was ensured with the invention of Pat Sullivan's *Felix the Cat* in 1917. Since the coming of sound the foremost place in this field has been held by Walt Disney, first with Mickey Mouse, then with the Silly Symphonies which first introduced an unexpected note of beauty into the film cartoon, and finally with such ambitious full-length cartoons as *Snow White* and the *Seven Dwarfs* and its successors, each necessitating over 20,000 separate drawings.

But by far the majority of films made are dramatic narratives (or photoplays, as they are called in the U.S.A.) enacted by professional actors from specially prepared scripts with a background, as often as not, of specially made scenery; and subsequently collated and given continuity and shape by expert "cutters." The primary purpose of such films is to entertain. Sometimes the stories are new; sometimes they are adapted from existing novels and plays. The source of origin of a film story does not in itself appear to affect either its box-office success or its worth as a work of art.

For better or worse, the general standards of film story, as well as those of acting and technical accomplishment, were set by the U.S.A., which obtained virtually a world monopoly in film production during the First Great War, and maintained its commanding commercial position for many years, Hollywood becoming the world centre of the film industry. For too long the general artistic level remained low. The box-office came first, and the average Hollywood silent film, designed to appeal to the uneducated masses throughout the world, was based either on sentimental romance, equivalent to that found in cheap novelettes, or on crude sensationalism. Humour, having a universal appeal, received a better showing, especially as an artistic genius in Charles Chaplin was found to show the way. But of wit, of intellectual content, of intelligent appreciation of human problems, or of insight into any but the most superficial human emotions, there was almost nothing. Technical achievement was immense, artistic achievement negligible.

#### European Developments

European countries approached the new art more seriously. The U.F.A. productions of Germany during the 1920s were in advance of their time, and their experiments in reflecting the researches of the psycho-analysts, as seen in such films as *The Cabinet of Dr. Caligari* (1919), attracted attention no less than their bold experiments in novel photographic "angles," unusual lighting, and atmospheric suggestion. Later German films, e.g. *Mädchen in Uniform*, *Westfront*, *Emil and the Detectives*, *The Captain of Köpenick*, were revolutionary in their delineation of character, their development of dramatic tension,

their accuracy in psychology. The experiments were abruptly ended in 1933 with the seizure of power by the Nazis.

France evolved a highly individual style of film drama, distinguished by a spritely and mordant wit, seen at its best in the early films of René Clair, e.g. *Sous les Toits de Paris* (1930) and *Le Million* (1931), but echoed in such later films as *La Kermesse Héroïque* (1936), *Un Carnet de Bal* (1937), *La Femme du Boulanger* (1939), and *Les Enfants du Paradis*, which was made during the German occupation. These memorable German and French films were made at trifling cost compared with the huge sums expended by Hollywood; nor were they great commercial successes.

#### Where British Films Excel

For some years after 1918 British film drama was mainly content with imitating the conventions of Hollywood. Such directors as Alfred Hitchcock, Anthony Asquith, and Alexander Korda were the first to establish artistic standards which were more satisfactorily indigenous, and by 1939 British films were ready to challenge comparison at least in quality with Hollywood products, whatever they lacked in quantity. A particularly happy vein was discovered in historical and biographical subjects, demanding a blending of accuracy in factual detail with imaginative treatment of character. A good example of this was Korda's *The Private Life of Henry VIII* (1934). Another British characteristic that has lent itself to successful treatment in British films is an affection for the authentic recording of familiar scenes and objects of daily life in and around the homes of ordinary people. British directors have been able to discover the stuff of appealing film drama in buses, trains, bicycles, motor coaches, suburban shops, village inns, factory canteens, humble breakfast tables, back yards, air raid shelters, and even, as in *Hue and Cry* (1947), the bombed ruins of London. One need search for examples no farther back than *Millions Like Us* (1943), *Tawny Pipit* (1944), *Waterloo Road* (1944), and *Brief Encounter* (1946). In place of the Hollywood formula of stock figures in startling surroundings, many of the best British films have offered all the rich oddities of native character against a background that is deliberately humdrum. The great heritage of English literature and

English drama, from Shakespeare to Shaw, provides another field for the British film which, in spite of isolated successes, has scarcely begun to be tapped.

That the Hollywood standards have slowly improved, however, becomes obvious if the list of awards of the American Academy of Motion Pictures, Arts and Sciences, is studied from its inception in 1927. The list includes *All Quiet on the Western Front* (1930), *Cimarron* (1931), *Mutiny on the Bounty* (1935), *The Life of Émile Zola* (1937), *Gone With the Wind* (1939), and *Casablanca* (1943), all films of considerable artistic achievement. To this list might be added *Mr. Deeds Goes to Town* (1936), *Green Pastures* (1936), *Louis Pasteur* (1936), *The Good Earth* (1937), *Citizen Kaffé* (1941), *The Best Years of Our Lives* (1947), and *Johnny Belinda* (1949). Moreover, from the coming of sound films and the consequent elimination of mere miming, American film actors, in spite of intense "off-stage" publicity, quickly schooled themselves to a natural style of acting which took British actors a whole decade to emulate. Hollywood's pre-eminence in the making of elaborate musical films remains unchallenged. So do the American comic films; there have been no British equivalents of the Marx Brothers, Laurel and Hardy, or Abbott and Costello.

#### Comparisons with the Stage

Compared with the stage, the film has proved itself to be unlimited in its range of subject. It can annihilate time and space, can portray a man's innermost thoughts, show a thousand actors at once or reveal the almost imperceptible twitch of an eyelid. With equal ease it enables the spectator to follow a procession through the streets of modern London or across the deserts of ancient Egypt. From the camera the spectator borrows an all-seeing eye; and among other things that eye cannot fail to catch many glimpses of beauty. The all-seeing eye moves rapidly. Shakespeare's *Romeo and Juliet* is divided into 22 scenes. Thalberg's film version had over 260, many of them no more than momentary. There were 239 separate camera scenes in *The Private Life of Henry VIII*.

The life of a film is short but intense, for it can be seen simultaneously in every part of the world. In Great Britain its life usually consists of a preliminary run at one or two cinemas in the

west end of London, followed immediately by a general and almost simultaneous release to the suburbs and provinces, where it is seen for no more than one week, and seldom again. After this it is assumed that everybody who wishes to see it has done so. A few cinemas specialise in the re-showing of earlier favourites, but general revivals are reserved for only an infinitesimal proportion of films. The British Film Institute (*v.i.*) compiles a valuable library of films as they are discarded by the trade, but their work began too late to save many of great historic interest.

#### Social and Moral Influences

This powerful art form has been made the medium for information, education, commercial advertising, propaganda (especially in the U.S.S.R., which nationalised its film industry in 1919), and, above all, entertainment. The extent of its social and moral influence has been debated from the very outset, ever since the exhibition in 1896 of a film called *The Kiss*. Much has been heard of the harmful influences of "the pictures": it is in the nature of things that any beneficial influences should remain unstated and incalculable. The moral effect of watching gangsters at work may well be balanced by that of watching policemen at work. Voluntary censorship on both sides of the Atlantic protects the public from certain excesses. For the rest, all that can be said with certainty is that the film-going habit has become deeply ingrained among many millions of the world's inhabitants, and that any improvement in the artistic standards of the commercial film is a sure reflection of improvement in public taste and public demand. See *Censorship*.

**Film Censors, BRITISH BOARD OF.** Organization established by the British film industry to formulate and administer a code of voluntary censorship of films produced or exhibited in Great Britain. The first president, G. A. Redford, was succeeded in turn by T. P. O'Connor, Edward Shortt, Lord Tyrrell of Avon, and Sir

Sidney Harris. The board has no legal power to enforce its code, but an exhibitor who offends may have subsequent supplies of films withheld, while a producer who offends may be refused facilities for exhibiting. A film banned by the board is not necessarily excluded from public exhibition: a local authority may decide that it may be exhibited. Also there is no control over films exhibited by private film societies.

The policy of the board is designed to safeguard morals, eschew politics, and to avoid the cruel or vicious in life. Films are not passed for exhibition if they include scenes depicting cruelty to animals; nor are films which might offend religious susceptibilities. Until May 10, 1941, when the building was destroyed, the headquarters of the board was at Carlisle House, Soho, built by Wren in 1670. See *Censorship: Hays Office*.

**Filmer, SIR ROBERT** (d. 1653). English political writer. Educated at Trinity College, Cambridge, he was a staunch royalist, and suffered much during the Civil War. His political treatises, mostly published posthumously, are of an absolutist character, defending the patriarchal theory of the origin of government, and attacking the doctrines of Hobbes, Milton, and others. The most important is *Patriarcha*, published 1680 and to which Locke replied in his *Treatise on Government*. Filmer died May 26, 1653.

**Film Institute, THE BRITISH.** Organization set up in 1933 to collect information, promote cooperation between teachers and the film industry, advise govt. depts. and schools on production and use of films, encourage research, and maintain a national film library. It receives an annual grant, at first derived from the Sunday cinematograph fund, later direct from the treasury, and has a board of governors representing govt. depts., educational bodies, and bodies connected with the film industry. As a result of a committee of enquiry under Sir Cyril Radcliffe, 1947-48, it was required to concentrate on encouraging the development of the art of the film, promote new uses for the film, and support other bodies with similar objects; and the governors were appointed by the lord president of the council. Its h.q. is at 164, Shaftesbury Avenue, London, W.1.

**Filmy Fern.** Ferns of delicate texture belonging to the genera *Trichomanes* and *Hymenophyllum*.

The leaves are so thin in substance that they are more or less pellucid, and lose moisture so rapidly that they are found growing only where the atmosphere is humid. Consequently in cultivation they require to be kept in a closed case. The filmy ferns proper form the genus *Hymenophyllum*, of which *H.*

Filmy Fern. Leaves of *Hymenophyllum tunbridgense*

*tunbridgense* is a well-known European form, with leaves only two or three inches long, growing in matted sheets on moist, shaded rock. The Killarney fern (*Trichomanes radicans*) is larger, with leaves as much as a foot long.

**Filon, PIERRE MARIE AUGUSTIN** (1841-1916). French author. The second son of the historian, Charles Auguste Filon (1800-75), in 1867 he was appointed tutor to the Prince Imperial, only son of Napoleon III, and after the Franco-Prussian War he accompanied the prince to England. He died at Croydon, May 13, 1916. Besides numerous studies of English life and literature contributed to French reviews, his voluminous works include *Guy Patin, Sa Vie et Sa Correspondance*, 1862; *Histoire de la Littérature Anglaise*, crowned by the Academy, 1883; *Nos Grand-Pères*, 1887; *Prosper Mérimée*, 1898; *De Dumas à Rostand*, 1898; and *La Caricature en Angleterre*, 1902. His son Louis (1875-1937) became a leading English mathematician.

**Filter.** Device for removing suspended matter from fluid. When matter is removed from a fluid by passing through a medium having holes smaller than the particles, for instance through wire gauze or perforated metal, the medium is a strainer rather than a filter. A filter proper may have holes very much larger than the particles removed, separation being effected by the trapping of the particles in the angles, narrow channels, and corners of the mass of the filtering body. In general, the greater the

thickness of the filter, the finer the filtration; a large thickness of a coarse body has the same effect as a smaller depth of a finer body; e.g. a layer 3 ft. deep of fine sand is equivalent to a layer one-eighth of an inch thick of fine kieselguhr.

A filter may take the form either of a sheet or of a mass of granular material held in a container. The commonest materials used as sheet filters are paper, cloth, porous stone, asbestos sheet, and sintered materials. Typical loose materials used as filters are sand, carbonate of lime, paper-pulp, powdered charcoal, kieselguhr, asbestos.

**SAND FILTERS.** Used mainly for the filtration of water, these are of three types: (1) slow sand filter, which is a layer of sand 2-3 ft. thick above a layer of gravel 1-2 ft. thick, covering often many acres. Water percolates through under gravity and is then pumped away. A rate of 1 to 2 gallons per sq. ft. per hour is usual; (2) rapid sand filter—a layer of sand in a large concrete open tank, used mainly for the preliminary purification of water from mud; it gives only a moderate degree of filtration; (3) pressure sand filter: in this, hydrate of aluminium is generally used in conjunction with the filter bed, which is enclosed in a cylindrical tank into which the water is pumped under pressure; a flow of 100 gallons per sq. ft. of filter surface per hour normally is attained. The filtering medium is fairly fine sand, and the pressure used does not in general exceed 20 lb. per sq. in. This type of filter is suitable for swimming baths and industrial installations.

**CLOTH FILTERS** can be classified under the following headings: (1) filter press (*q.v.*); (2) rotary filter, the usual type of which is a horizontal drum divided into separate sector compartments, the curved surface being covered with filter cloth. The filter is mounted to rotate on its longitudinal axis half submerged in the liquid to be filtered. As each section becomes submerged a valve puts it into communication with a vacuum pump which draws the liquid through the cloth surface, leaving the solid to form a cake on the outside. When in the course of the rotation the section emerges from the liquid the suction is continued to dry the cake, and sometimes wash water is applied at this point. Before the drum completes a revolution, the cake is scraped off by a stationary knife, or blown off, or otherwise removed, and the cloth surface thus cleaned is ready

for another cycle; (3) bag filter: this usually consists of a number of bags, each about 6 ft. long and 9 ins. in diameter, their necks tied each to a short pipe by which liquid enters the interior of the bag from a tray supplied with the liquid to be filtered. Each pipe fits tightly into a hole in the bottom of the tray. This filter is effective in removing slimy deposits where high pressures are inadmissible; (4) gravity filter, which consists of cloth bags with a drainage frame inside them. Several are supported in a closed tank to which liquid is supplied under a pressure of 10 to 20 ft. gravity head. The liquid flows through the cloth into the centre of the bag and a nipple provides an outlet through a liquid-tight joint to the outside of the tank, where the filtrate is collected in a gully.

There is a very large variety of filters using finely porous material such as unglazed porcelain, compressed asbestos, compacted kieselguhr, or edge-filtration through paper. The "Metafilter" (Fig. 1), suited to fine clarifications of many different types, is a combination

of a metal edge-filter (in which the filtering surface is made up of the edges of a large number of rings spaced accurately a few thousandths of an inch apart) with a fine filter bed, such as powdered carbon or kieselguhr, forming a layer over it and firmly supported by the metal sub-structure. The actual filtering is carried

out by the bed; the porosity and chemical or physical nature of this can be varied to eliminate bacteria or remove precipitates, to withstand chemical attack or temperatures from below 0°C. up to red heat.

The "Streamline" filter was developed from a discovery made during the study of streamline flow, when it was found that paper joints separating sheets of glass between which the shape of streamlines was being studied had the effect of permitting flow past their edges and at the same time removing

Filter. Fig. 1. Metal edge filter which uses the spaces between a number of metal rings as the filtering medium

extremely finely divided material. This discovery gave a filter in which many sheets of suitable paper were superimposed with their edges all in line to form a filtering surface. In the filter shown in

Filter. Fig. 2. Paper pack (left) and filter body (right) for edge filter.

Fig. 2, the paper rings composing it are about two inches in diameter with a half-inch diameter hole, forming a drainage pipe in the middle. The pack is mounted in a filter body, and liquid forced through from the outside to the central hole, by pressure or by suction. The solids collect on the outside. This type of filter is fine enough to remove colloidal particles.

In the "Ultrafilter" (Fig. 3), the filtering medium is a film of excessively fine porosity, often produced by treating a surface with a solution of nitro-cellulose and precipitating the cellulose by immersion in water. The resulting translucent

Filter. Fig. 3. "Ultrafilter" which can be used for pressures up to 12 atmospheres with about one sq. in. of filter surface. Funnel (D) carries the filtering membrane on the perforated plate and is clamped by wing nuts to cone (C) containing liquid. Cover (B) is tightened and pressure applied through regulating valve (A). Left. Filter assembled

film is covered with tiny pores, small enough to prevent the passage of colloidal particles down to one hundred-thousandth of a millimetre. The "Ultrafilter" works by straining and is consequently very easily cleaned by backflushing; but the technique of its use is difficult, as the film is excessively delicate and the filter usually has to be operated under very high pressure. Construction of a large size "Ultrafilter" is scarcely practicable.

Filter. Fig. 4. Asbestos fibre sheets mounted on a press frame with screen mechanism for tightening  
Courtesy of British Filters

A filter of unglazed porcelain is still widely used for the filtration of water for drinking. The action here also depends on the extremely fine pore size of the material. The pores, although larger than those of the "Ultrafilter," will remove bacteria, but not viruses.

The filter is usually a hollow cylinder with a spigot outlet projecting through the bottom of a container. It is easy to use, but difficult to clean on the outside and impossible to clean on the inside. A similar filter is made from kieselguhr lightly cemented and pressed into solid form; this removes bacteria and filters quicker than a porcelain filter; it is even more fragile.

A widely used type of filter is made of sheets of compressed asbestos fibre, sometimes of varying degrees of porosity but with a closeness of structure sufficient to remove bacteria and spores. The

sheets are mounted in a specially constructed press (Fig. 4), built closely on the lines of a filter press. Though the asbestos sheets, which are expensive, can be cleaned to some extent by washing, it is generally found that they have to be discarded rather frequently.

The sintered glass filter (Figs. 5 and 6) is popular for laboratory use. Glass particles are first classified by sieving within suitable dimension limits, and then heated in layers of the right thickness to near melting point, which causes them to adhere together. Porosity precise to almost any desired degree can be obtained in this medium. See Filter Press; Filtration.

**Filter Press.** Device for separating solids from liquids by filtration under pressure. The earliest filter presses consisted of frames

supporting filter cloths placed side by side or piled upon one another and held together in a screw press. This structure is still the basis of a filter press; but pressure is now applied to the liquid to force it through the assembly, and it is this pressure,

rather than that holding the plates together, which is in mind when the filter press is referred to.

There are two main types of filter press: (1) for removal and collection of precipitates from liquids, the usual filter press; (2) for the expression of liquids from solids, often called an extraction press.

Filter presses proper can be subdivided into (a) the recessed plate type filter and (b) the flush plate

Filter. Fig. 5 (left). Sintered glass discs which can be used in ordinary funnels. Fig. 6 (right). Funnel of Buchner type with the sintered glass septum fused in

and distance frame filter. Both types when in operation consist of a series of chambers having walls covered with filter cloth, provided with drainage channels which lead down to filtrate outlets (see Fig. 1, p. 3338). The filtering frames covered with cloth are mounted vertically so as to face each other and slide on the side members of the press frame and are tightened by the operation of the screw mechanism. The liquid enters the press at the far end and emerges from both frames through the filtrate cocks shown at the sides, the filtered liquid being collected by the trough.

The internal construction of a recessed plate filter is shown in Fig. 2 (p. 3338), of a section through the closing head and the first chamber. This press has centre feed. A, A1, and A2 are filter plates forming chambers

B, B1, and B2, into which the material to be filtered enters by means of inlet D. The outlets for the filtrate connect to the ports marked E. The rims C of the plates are machined so that when the plates are tightened into position, the cloth makes tight joints between the plates. Each chamber is thus completely lined with cloth so that, when the material to be filtered is forced in under pressure, the solid particles are retained by the cloth, and the liquid portion, freed from suspended matter, passes through to the outlet.

A filter with flush plate and distance frames is shown in Fig. 3 (p. 3338): F are the filter plates and D the distance frames which form the chambers. A is the inlet passage for the material, having ports B connecting it to the interior of the chambers. C are

ports connecting to the outlets for the filtrate which may terminate in cocks or run into a common closed delivery passage. The plates have faced joint surfaces flush with the filtering surface, the chambers being formed by hollow frames with plane surfaces corresponding with those of the plates between them. The cloths are hung over the plates so that each chamber has a cloth on both sides.

Filter presses are convenient where moderate proportions of solids, say up to 10 p.c., have to be removed from the liquids. They are used until the space within is filled with solids, which can be washed out, without taking down the filter, by passing water through it.

Filter presses require rather more labour than some other types of filter, but are almost indispensable for many operations,

Filter Press. Fig. 1. Cloth filter frames mounted vertically and compressed by an operating screw; trough for collecting filtered liquid is seen at left

particularly in chemical manufacture, in which steam heated models are sometimes used. They are usually constructed of cast iron, but can be made in almost any metal. Their surfaces are protected from attack by many different coatings. Cloths are also made in many different qualities and grades to suit different needs.

Extraction presses are used chiefly in the separation of oil from nuts and seeds. Before the material is put into the press, it is prepared, usually by grinding and heating. The Anglo-American or plate type of press, which produced flat rectangular residue cakes, was rather laborious in use: it consisted of a large number of frames or trays, piled one on top of another, each of which had to be packed separately with extraction material. Pressure applied to the whole pile expressed most of the oil, but some remained in the margins of the cake, and these had to be trimmed off and re-pressed.

The continuous automatic oil expeller tends to displace the plate press. Prepared meal is placed in the cooker above the expeller (see Fig. 4). Steam valves closely control the temperature and moisture content of the meal, which is fed through an adjustable valve to the expeller-pressing cages. Here the cooked meal is subjected to heavy pressure by means of specially shaped and pitched worms, and is propelled through the cage in a continuous column and finally discharged at the cage end past an adjustable

choking device which determines the final pressure applied. The expressed oil leaves the cage through bars which form the cage lining, set at five-thousandths to fifteen-thousandths of an inch apart, depending on the material. The expelled cake is in

water, without danger of disease, filtration is essential.

Two general types of filter are in use: (1) the slow sand filter (*v.s.*), first used in Great Britain early in the 19th century. It depends substantially on biological activity for its efficiency, and is controlled largely by climatic conditions; (2) the rapid or mechanical sand filter, developed during the 20th century. This has greater flexibility and is more amenable to control.

Slow sand filters are now seldom constructed except as additions to existing plant. They consist of rectangular brickwork or concrete basins, on the bottom of which are channels, perforated pipes, or other under-drains supporting gravel on which rests a bed of sand. The under-drain system must be so designed that its frictional resistance when the filter is operating does not exceed 25 p.c. of the frictional loss occurring in the sand when it is clean. During operation the water depth over the sand is generally 4 ft. when the sand is at full depth, which should be 2 to 3 ft. above 1 to 2 ft. of gravel. The sand should be hard, durable grains, free from impurities such as clay, iron, sulphates, phosphates, and organic

thin flakes of irregular shape up to  $\frac{3}{8}$  in. thick, and is quite hard when cold.

**Filtration.** Process of removing fine solids from liquids. The two uses of the process of most interest to the general public are in the purification of water supplies and of sewage. Most waters require treatment either for the removal of disease germs and unpleasant taste and odour, or for the elimination of gases, murkiness, and colour. Methods of treatment are storage and simple sedimentation; rapid sedimentation with chemicals as coagulants, followed by filtration. To produce a clear, sparkling

Filter Press. Fig. 4. Continuous extraction press for the expressing of oil from oil seeds. This type of press has the advantage of continuous productivity as against batch pressing

matter, and should be carefully graded. Rate of flow through the bed, which is downwards, is usually between 2 and 6 inches an hour, equivalent to from 1.1 to 3.3 million galls. per acre per day, at which rate it is reasonable to expect that 98 to 99 p.c. of the bacteria have been removed. The greater part of the purification of the water is effected in the top few inches of the bed, which is cleansed by scraping off the top layer and exposing a fresh surface of sand. The sand removed can be washed and replaced. It is not advisable to

reduce the sand bed by more than a foot before replacement. After cleaning, the beds are refilled with filtered water from below until the sand is completely covered, thus preventing the entrapping of air in the sand.

Rapid filters are of two types, the open gravity filter and the closed pressure filter. The essential characteristics are (1) careful pre-treatment of the water; (2) high rate of filtration, the speed varying from 60 to 150 galls. per sq. ft. per hr. according to the character of the water to be filtered (100 galls. per sq. ft. per hr. is equivalent to approximately 105 million galls. per acre per day, and this rate is in fairly general use); (3) washing the filter units by a reverse flow of filtered water upward to remove impurities which have lodged in the sand.

The filters are built in units which are constructed usually of concrete for the open gravity type, and of steel cylinders for the closed pressure type. They contain a bed of sand resting on gravel, with suitable water distributing arrangements at the top and under-drainage system at the bottom. In some filters, compressed air is admitted as part of the back-washing process, and in others the sand bed is agitated mechanically during washing. The sand

Filtration. Slow sand filter-bed at a Metropolitan Water Board's London works. Workmen are seen shovelling the sand-bed into heaps before the process of washing and relaying of the sand, preparatory to a new fill-up of water

used should be free from dirt, hard and resistant, and preferably of quartz or quartzite. It should not contain more than 2 p.c. of lime and magnesia calculated as carbonates. The effective size specified is between 0.44 mm. and 0.6 mm. and the uniformity coefficient not more than 1.7. The depth of the sand bed should be  $2\frac{1}{2}$  to 3 ft., of the supporting layer of graded gravel 1 to  $1\frac{1}{2}$  ft., and of the water above the sand 3 to 4 ft. The sand removes bacteria, finely divided clay, and colloidal matter even smaller than the sand grains, and this is accounted for by the fact that the minute void spaces act as small sedimentation chambers, permitting the suspended particles to come in contact with the sand surfaces which soon become sticky, particularly if small amounts of floc come into the bed from the coagulation process. There is soon accumulated in the top few inches of the sand various suspended matters which form a dense blanket of mud, floc, and living or dead organisms, which is called *schmutzdecke*, or dirty skin. It is possible, also, that removal of colloidal matter is brought about by sand particles which have an opposite electrical charge to the ions of the colloids, the grains attracting colloidal matter until their charges are neutral-

ised. The accumulated material is removed by washing, and the sand's electrical charge is restored.

Rapid filters are considered the more desirable in ordinary circumstances, although there is a field for the slow filter where the water is very clear and requires preliminary treatment for a limited time only. The over-all bacterial efficiencies of the two types are the same. The slow filter requires less skill in operation; generally costs less to operate; uses less wash-water. The rapid filter will clear more turbid water; is more efficient in colour control; has greater flexibility in operation because it involves chemical pre-treatment; involves less interruption of service during cleaning; is lower in first cost, taking into account the cost of land. (*Consult Examination of Waters and Water Supplies*, E. V. Suckling, 5th ed., 1943.)

SEWAGE. Biological filtration, used at the majority of sewage disposal works in Great Britain, developed from earlier systems in which sewage was allowed to percolate downwards through porous soil, the liquid then being drained away through agricultural drains laid at a distance of 3 or 4 ft. from the surface. The sewage is first passed through screens and detritus channels to remove coarse suspended solids and grit and is

treated in sedimentation tanks in which a large proportion of the fine and colloidal suspended matter is removed. Supernatant liquid from these sedimentation tanks is treated in percolating filters.

A percolating filter is designed to purify the settled sewage rapidly by biological action. It comprises (1) a concrete base sloping to the centre or to the periphery in such a way that the filtered sewage easily runs away to collecting channels; (2) a system of underdrains resting on the base and designed for rapid and easy removal of the filtered liquid; (3) a wall to retain the filtering medium; (4) a bed of filtering medium; (5) a distributor through which the settled sewage is supplied evenly over the surface of the filter.

#### The Filtering Medium

The filtering medium should be well graded; the size of the pieces differs for different purposes, but is commonly from 1 in. to 2 ins. The chief requirements of the filtering medium are that it should be durable and chemically inert. Material used on a large scale includes water-worn gravel, broken stone, metallurgical coke, slag, and clinker. In Great Britain the depth of filtering medium is commonly 6 ft. It is very important that there should be a free current of air through the bed of medium, and for this reason ventilating holes are provided at the bottom of the retaining wall to induce an upward draught of air through the filter. The even distribution of settled sewage over the surface of the filtering medium is usually achieved by passing it through fixed sprays, or through rotary distributors (for circular filters), or through distributors moving backwards and forwards (for rectangular filters).

It is usual to start new filters by applying settled sewage at a low rate, the dose being gradually increased as the pieces of medium become coated with the biological film of material from the sewage containing bacteria and, especially at the surface, fungi, and providing food for numerous other organisms which live in the spaces between the pieces of medium. The most important types are springtails, worms, and the larvae of certain flies. These "scouring" organisms play an important part in restricting the excessive growth of biological film which might otherwise choke the filter. Adult flies, however, emerging from percolating filters sometimes cause a nuisance, and it may be necessary

Fin. Diagram of the outline of a fish showing the positions of its various fins

to treat a filter with insecticide to reduce the number of fly larvae.

Settled sewage contains colloidal organic matter which it is impossible to remove by further sedimentation. Effluent from a percolating filter contains coarse suspended matter ("humus") consisting partly of pieces of biological film broken away by the action of the scouring organisms. This humus can fairly readily be removed by sedimentation in humus tanks. Settled sewage may have a biochemical oxygen demand of 25 parts per 100,000; it usually contains no nitrite or nitrate, but may contain perhaps 5 parts per 100,000 of nitrogen in the form of ammonia. A settled filter effluent should have a biochemical oxygen demand not exceeding 2 parts per 100,000, and most of the ammonia should have been oxidised by biological action to nitrate.

The permissible rate of filtration of settled sewage to yield an effluent of good quality depends on the strength of the sewage, but for a liquid of average strength is usually of the order of 60 to 90 gallons per cubic yard of filtering medium per day. If the permissible rate is exceeded the growth of biological film in the filter may increase to such an extent as to cause first "ponding" on the surface of the medium, and finally complete blockage of the filter. At the same time the quality of the final effluent would usually deteriorate. Advances in the technique of biological filtration, however, have made it possible under favourable conditions to increase considerably the rate of treatment of the settled sewage. Current systems of filtration include (a) treatment in covered filters with forced circulation of air from the top downwards, (b) filtration of settled sewage mixed with settled effluent pumped back from the humus tanks and mixed with the settled sewage before application to the filter, and (c) alternating double filtration.

to treat a filter with insecticide to reduce the number of fly larvae.

Fin. In aeronautics, any fixed subsidiary vertical plane or surface usually at the rear part of the fuselage of an aircraft. The fin is generally mounted in front of the rudder, and its purpose is to increase the stability of the machine. A cooling rib of metal formed on the cylinder of an engine is also termed a fin. Its purpose is to facilitate the radiation of heat from the engine and prevent overheating. Fins are fitted to paravanes (*q.v.*) to ensure their remaining at a constant depth when submerged, and largestabilising fins are fitted to the rear of some racing cars to keep them on a level course when travelling at high speed. See Aeroplane.

Finale (Ital., *end*). Closing movement of a composition of extended character, such as a sonata, symphony, or concerto; or the last portion of one of the acts of an opera, in which as a rule a large number of the performers assemble on the stage. The operatic finale often consists of several distinct movements, but all leading up to the final ensemble. As the coda is the concluding section of a single movement, so the finale winds up a complete work consisting of several movements. During the past two centuries the coda and finale, from being mere perfunctory endings of little significance, have become an important summing up and climax.

Finance (late Lat. *finare*, to pay a fine). A word used for money matters in general, but especially for those of a country, town, or other corporate body. See Consols; National Debt; National Finance.

Finance Act. Name given to the annual Act of Parliament that legalises the proposals contained in the budget (*q.v.*).

Fin of an aeroplane

**Financial Times**, THE. London newspaper, founded in 1888, published daily at twopence. It reports all financial matters, company meetings, and stock exchange dealings, making careful industrial and economic surveys and studies of trade prospects. From time to time illustrated supplements are included in the ordinary issue, dealing with trade conditions in foreign countries. In 1924 the *Financial Times* absorbed the *Financier* and *Bullionist*, an amalgamation of two journals begun respectively in 1870 and 1866. In 1945 it was merged with the *Financial News* (founded 1884), though its title was retained. It has the largest circulation of any financial paper in the British Empire. Its printing works are at St. Clements Press, and its head office at 72, Coleman Street, E.C.2.

**Finch**. Name applied to a large family of small birds, Fringillidae, distributed over most of the temperate zone, except Australasia. They are characterised by hard conical beaks, and have nine primary wing feathers and twelve feathers in the tail. The nostrils are close together, and there are a few short bristles around the mouth. In most species the sexes are differently coloured or marked. Finches are in the main seed-eaters; they are commonly found in small companies, and they frequent both woods and open country. Among the commoner finches in Great Britain are hawfinch, greenfinch, chaffinch, brambling, goldfinch, siskin, linnet. See Brambling illus.

**Finch, JOHN FINCH**, BARON (1584-1660). English politician, born Sept. 17, 1584. Elected Speaker of the house of commons in 1628, he figured in a scene when he was held down in his chair during Sir John Eliot's remonstrance against tonnage and poundage. Chief justice of the common pleas in 1634, he presided at Hampden's trial for refusal to pay ship money. A zealous servant of the crown, Finch was made lord keeper and a peer in 1640, but was later impeached and spent years in exile during the Civil War and Commonwealth. He died Nov. 27, 1660, in England. *Consult* Life and Times, W. H. Terry, 1936.

**Finchley**. Residential bor. and par. div. of Middlesex, England. Lying E. of Hendon, N. of Golders Green, Hampstead, and Highgate, and S. of Whetstone and Barnet, it is approached from St. John's Wood by the Finchley Road, from Highgate by the Great North

Road; these roads converge at Tally Ho corner (N. Finchley). The bor. is served by London Transport. It contains Church End, and part of Hampstead garden suburb. Near the Perpendicular parish church of St. Mary, restored in 1872, is Christ College, founded 1857. About 90 acres of what was Finchley Common, once a resort of highwaymen and the scene of several military encampments, are occupied by the Islington and St. Pancras cemeteries; St. Marylebone cemetery is between East Finchley and Church End. General Monk mustered his forces here in 1660, and the Guards were assembled here in 1745, an event commemorated in Hogarth's picture, *The March to Finchley*. Finchley joins the urban district of Friern Barnet to return one member to parliament. Pop. est. 66,000.

**Finck, HERMAN** (1872-1939). British conductor and composer. Born in London, Nov. 4, 1872, he studied at the Guildhall School of Music, was musical director of the Palace Theatre, London, 1900-21, and at Drury Lane, 1922-31. He composed music for many musical comedies and revues, as well as hundreds of songs and light pieces, of which the most popular was *In the Shadows*. He also specialised in attractive arrangements of popular airs, his *Melodious Memories* (over 70 tunes in 15 minutes) being a masterpiece of its kind and giving its name to his autobiography, published 1936. He died April 21, 1939.

**Findhorn**. River of the counties of Elgin, Nairn, and Inverness, Scotland. It issues from the Monadhliath Mts., and flows N.E. for 62 m. to Moray Firth, which it enters 2 m. N. of Forres through Findhorn Bay. Findhorn, a fishing village and watering-place, is on the E. shore of the bay.

**Findlay**. City of Ohio, U.S.A., the co. seat of Hancock co. On the Blanchard river, 44 m. by rly. S.S.W. of Toledo, it is served by several rlys. and an airport. Findlay is situated in an agricultural, oil, and natural gas region. Agricultural products include livestock, poultry, grain, and sugar beet; manufactured articles, lorry bodies, motor car parts, tires, cigars, gloves, brick, stone, and lime. Laid out in 1821, it was incorporated in 1838, and chartered as a city in 1890. Pop. 20,228.

**Findlay, SIR JOHN GEORGE** (1862-1929). New Zealand statesman. He was born at Dunedin,

Oct. 21, 1862, and went to Otago university. After being prominent as a lawyer he became attorney-general, minister of justice, and colonial secretary. In 1911, with Sir J. Ward, he represented New Zealand at the Imperial Conference. Ever a strong advocate of Imperial federation, he made a special study of the problems of Imperial policy in the Pacific. He died Dec. 7, 1929.

**Findon**. Village of Kincardineshire, Scotland. It is on the coast, 6 m. S. of Aberdeen. Fishing is carried on, and the village gives its name to the Findon or Finnon had-docks, which were first cured here.

**Fine** (Lat. *finis*, the end). Term common in English law. Originally it was a sum of money imposed upon someone by way of compounding, i.e. paying to make an end of the matter instead of going to prison or paying in several instalments. By feudal law a leaseholder often pays a fine for the renewal of his lease. The word is most often applied to a sum of money imposed as a penalty for a criminal offence or breach of some law or regulation. The maximum is usually fixed by a statute, the exact amount being decided by the court; but during the Second Great War fines unlimited in amount could be imposed on companies for breaches of Defence Regulations.

**Fine Arts**. Term comprehensively embracing all the five greater arts which minister to the love of the beautiful, the intellectual, and the tasteful, viz.: music, poetry, painting, sculpture, and architecture. Custom, however, has confined the term to the last three particularly, and these again include allied subjects, such as engraving, decoration and design. The French term *Beaux Arts* has a similar significance.

**Fine Gael**. Name of the Irish political party—meaning "stock of the Gael"—formed of the remnants of the Cosgrave (*q.v.*) pro-treaty party in Dáil Éireann which was in power in the Irish Free State from 1922. In 1932 it was heavily defeated by Eamon De Valera's Fianna Fáil (*q.v.*), becoming the opposition party for 16 years. At the 1948 elections Fine Gael secured 31 seats and was again the chief opposition party. Combining with other parties to outvote Fianna Fáil, Fine Gael supplied in J. A. Costello a leader for a coalition govt.

**Fines and Recoveries**. Legal fiction introduced in England to override an Act of Parliament

which was against the public interest. By the statute *De Donis Conditionalibus* (on conditional gifts) in 1285, it was enacted, in effect, that land which was entailed could never be disentailed; so that if an estate were given or left to A in tail, it must always keep in A's family and could never be sold. By this, among other things, the creditors of A, or his heir in tail, could never touch the land for their debts. The judges were strongly opposed to the policy of the barons who had passed this Act, because they thought it against the public interest that land should be made inalienable.

Therefore from about 1400 they connived at fines and recoveries, which were fictitious actions worked thus. A is the holder in tail of Whiteacre. He wishes to disentail, so that he can sell or mortgage, or divide his land amongst his family. An action is brought by X, claiming the land from A, X alleging that the land was his in fee simple (*q.v.*). A, on getting into court, says that the land was granted to him by Q, who was in fact, the usher of the court; Q was then called upon to come into court and defend his title. Of course Q put in no appearance. Judgement was thus given in favour of X; and X, having recovered the land as a fee simple, promptly reconveyed it to A as a fee simple, free from the entail. By an Act of 1833 fines and recoveries were abolished. See *Fiction, Legal*.

**Fingal's Cave.** Cavern in the island of Staffa, Scotland, the most notable of its kind. Hollowed out of the basalt, the grotto is 228 ft. long, 48 ft. wide, and 60 ft. high. It is remarkable for its regular basaltic columns, for its wonderful and varying colours revealed as the light plays upon it, and for its stalactites. On the S. of the island, it was discovered by Sir Joseph Banks in 1772. Sea birds live in the

Fingal's Cave, Staffa. The pillared entrance to the grotto

cave, which is also noted for the sound made at times by the wind rushing out of it. In Gaelic speech it is called the cave of music. Mendelssohn's overture, op. 26, alternatively called *The Hebrides* or *Fingal's Cave*—composed 1829—is regarded as one of the finest portrayals of the sea in music.

**Finger.** Terminal member of the hand. The bones or phalanges of the fingers are three in number

Finger. Bones of human fingers

in each finger, except the thumb, which has only two. The fingers articulate with the metacarpal bones of the palm. Along the backs of the fingers pass the tendons of the extensor muscles, which straighten the fingers, and along the fronts the tendons of the flexor muscles, which close the hand. The blood supply of each finger is derived from two digital arteries which run along each side of the finger and unite at its extremity. The nerves which supply the skin are derived from the ulnar, radial, and median nerves.

The digits are named pollex, or thumb, index, medius, annularis, and minimus.

**Supernumerary** fingers are not uncommon. In a case on record there were twelve fingers on one hand and thirteen on the other, and twelve toes on each foot. Absence of one or more fingers, or part of a finger, may also be a congenital deformity, *i.e.* present at birth. In webbing of the fingers, or syndactylism, a thin web, usually consisting chiefly of skin, unites one or more fingers. Sometimes the union is thick and fleshy. See *Anatomy*.

**Finger and Toe.** Disease causing malformation of the roots of turnips and other cruciferous crops also known as club-root (*q.v.*).

**Fingerboard.** Portion of a stringed instrument against which the fingers press the strings in order to regulate the vibrating lengths of the strings, and so control the pitch of the sounds. Bowed

instruments of the violin family have smooth fingerboards on which the player must judge and remember the correct stopping-places; the plucked instruments such as the guitar, mandoline, and banjo usually have frets or cross ridges to assist the player.

**Finger Print.** Impression of the human finger. It is used to classify human beings; but chiefly for the identification of persons who have passed through the hands of the police. The individuality of finger prints and their value in proving identity were known to the Chinese about 200 B.C., and an impression of the thumb was used in lieu of signature; but it was not till the 19th century that the classification of the ridges on the finger tips was attempted.

**Finger Print.** Two diagrams illustrating (upper) the actual thumb print in blood left by a murderer, and (lower) the lines of the ridges of this thumb print drawn to facilitate examination. The letters from A to S indicate the various characteristics which distinguish the print, *e.g.* L is the bifurcated ridge, S B is the line joining the two terminal points of the print, to enable the number of ridges to be counted and compared with a known thumb print of the murderer, who was caught and sentenced on the evidence furnished by these two diagrams

In 1823, Purkenje, professor of physiology at Breslau, suggested a system of classification, and in 1858 Sir William Herschel laid the foundations of the present system in Bengal. In 1890 Sir Francis Galton pointed out that ridges on the fingers of a new-born infant were absolutely identical to the day of death.

The full value of Purkenje's, Herschel's, and Galton's work was recognized when Sir Edward Henry devised a numerical formula for classifying the impressions. The Henry system has been widely adopted by the police organizations of the world. Under the American Seaman's Law of 1915 the finger prints of every sailor in the American merchant marine were taken for classification of able seamen, etc., and the prevention of fraud; while in the war department finger print records are kept of every soldier. It has been shown that the chance of identity of two finger prints is less than one in sixty-four thousand millions, and the prints of one finger, therefore, are enough to decide the question of identity. If, as is customary, the prints of three or more fingers are taken possibility of error is eliminated.

All finger print impressions are divided into two groups of four types and eight distinct patterns, such as loops, arches, etc. The ten fingers in the Henry system are divided into five pairs, and by a special way of numbering these pairs the classification of a particular finger print is made simple. See Criminology.

**Fingo** OR **AMAFENGU** (Zulu, wanderer). Collective name for Bantu-speaking peoples of Kaffir stock whose tribal unity was destroyed by the Zulus under Chaka. In 1835 the Cape government gave them asylum near the Great Fish river; this Fingoland reserve became, in 1877, one of the Transkei districts. Always friendly to the British, they have become largely Europeanised and Christianised, with a high educational standard. They furnish labour contingents for the harbours and mines.

**Finial** (Lat. *finis*, end). In architecture, a foliated ornament capping a pinnacle, gable, or stair-post. Occasionally the finials of stair-posts themselves acted as supports for statuary, like those at Cromwell House, Highgate, where they are surrounded by Roundhead figures.

Finial. Example from Canterbury Cathedral

**Finiguerra**, MASO (c. 1426-64). Italian goldsmith and engraver, born probably at Florence. Details of his life are uncertain. He was trained as a goldsmith in the workshop of the Pollaiuoli. He is stated by Vasari to have invented engraving on metal, but he was only one

of the pioneers in this craft, which he practised together with niello work, of which he was a master. Intarsias by him are to be seen in the sacristy and the cathedral museum, Florence; his prints and drawings are in the Uffizi gallery and the British Museum. There has been much controversy as to his alleged invention of engraving.

**Fining** (Lat. *finis*, end). Process by which liquids are freed of solid matter and impurities, and thus clarified. Though somewhat akin to filtering, it is used in a special sense in the brewing and distilling industries, various substances such as isinglass, sulphate of lime, etc., being employed to collect and carry off the matter in solution, leaving the liquid bright and clear. In fining syrups white of egg may be used, the albumen being dissolved by heat. Wines are similarly fined without the application of heat, the alcohol acting as the solvent. (See Brewing; Distilling.) Fining is also a process in glass-making, and was used in the production of malleable iron before puddling was introduced.

**Finistère**. Dept. of France. In the extreme N.W. of the country and part of Brittany, it is bordered by the sea on three sides. The Aulne is the most important river. The

coast is rocky and broken, but contains some good harbours. Off it are Ushant and other islands. The dept. is hilly, though not mountainous, and much of the land is covered by forest and heath, useless for growing crops. Elsewhere, however, especially in the south, there is fertile land which produces asparagus, onions, and other vegetables, as well as apples and fruit. Oats and wheat are grown; cattle and horses are reared, while the peasants also keep bees and make butter. Many of the inhabitants are employed in the fisheries. The dept. has five arrondissements. Quimper, liberated by the F.F.I. Aug. 9, 1944, is the capital town, but Brest, centre of a fierce battle, Aug.-Sept., is the most important. Morlaix is also a flourishing port. With the surrender of the Germans in Brest, Sept. 19, 1944, the whole department was liberated. Area, 2,729 sq. m. Pop. 724,735.

**Finisterre**. Cape on the N.W. extremity of Spain, in the prov. of Corunna. Off the cape two naval actions were fought in 1747 between the British and French, resulting in the defeat of the latter. Admiral Anson commanded the British forces on May 3, and Admiral Hawke on Oct. 14.

## FINLAND: LAND OF FOREST AND LAKE

*The history and social organization of the Finns, a small, progressive, energetic, and independent-minded people, and a description of the geography of their lake-studded country are given here, together with a brief account of the two wars they fought with Russia between 1939 and 1944. See also in N.V.*

Finland, a republic of N. Europe, lies between Russia on the E., Sweden and the Gulf of Bothnia on the W., Norway on the N., and the Gulf of Finland on the S. Its greatest length is 717 miles, its average breadth about 185. In area it is rather smaller than Great Britain and Ireland. Helsinki (pop., 1943: 327,627) is the capital.

Finland's coast-line, which is entirely on the Baltic, is 1,000 m. long, low-lying, highly indented and fringed with islands of which the Aaland Is. (q.v.) in the S.W. are the most important. The country consists of a great plateau, at an elevation of 400 to 600 ft., with lowlands round the coast. The surface of the land consists of hard and crystalline rock, granite, etc., for the most part covered with a thin layer of infertile sands and clay. Drainage is bad and the soil is water-logged during most of the year. The southern half of the plateau has about 25 p.c. of its area occupied by thou-

sands of shallow lakes, many of them linked by short natural and artificial channels. In the N. the plateau is more elevated and rugged, rising in many places to heights of over 2,000 ft., but there are no well-defined mountain ranges. The northern part of the country is Lapland and is inhabited by the nomad race of Lapps.

Marsh and bog have occupied about 30 p.c. of the country, but the bog area is being diminished by the united efforts of nature and man. About 12 p.c. is covered by lakes, of which there are more than 60,000. In the S., 120 large lakes and several thousand small ones, all connected and having a natural outlet into Lake Ladoga, spread over an area 502 sq. m. Lake Ladoga, once partly in Finland, but now wholly within

Finland arms

Russia, is adjacent to the Imatra falls (or rather rapids) which for scenery are the finest of their kind in Europe and in volume of water the greatest. There are numerous short rivers broken by rapids and navigable only in stretches, but useful for floating timber. Many of them are well supplied with fish, but are more important as a source of water-power—often severely curtailed by frost in winter and drought in summer.

#### Forests and Animals

Finland is relatively the most wooded country in Europe, more than half the land surface being under forest. Two-fifths of these woods are owned by the state, the rest privately. A law of 1917 prohibits the reckless felling of timber by private individuals. Scots pine and Norway spruce are the most widespread of the trees and the most profitable; after them come birch, alder, ash, and oak. Among wild animals are bear, fox, lynx, ermine, otter, elk, and hare. The wild reindeer and beaver, formerly abundant, are now extinct. There are over 200 species of birds, not counting the domestic sorts. Seals

are plentiful along the coast and in Lakes Saima and Ladoga. In the rivers, lakes, and seas of Finland there are some 70 species of fish, the most abundant being a kind of herring off the S. and S.W. coasts. It forms an important element in the food of all classes; large quantities, both smoked and salted, are stored for winter. Most of the rivers yield salmon, trout, perch, or pike.

The climate, owing to the prevalence of moist W. and S.W. winds, is less severe than it is farther east in corresponding latitudes. In Jan. the average monthly temperature varies from 90° F. about Lake Enare to 30° along the S. coast; while in July the difference between the monthly averages is only 8°, being 53° in the N. and 61° in the S.E. Everywhere, and especially in the interior, the winter lasts a long time. The summer is short, occasionally very hot in June and July, when the mosquitoes can be a plague. But the long summer days, with the sun only for an hour or two under the horizon, have a peculiar charm.

The dominion of the Swedes was very unfavourable to anything like a Finnish literature, the writers of Finland preferring to write in Swedish and so secure a wider audience. It was not until 1835 that the Kalevala appeared, an epic poem formed by E. Lönnrot (1802-1884) out of a collection of popular songs taken down from the lips of the peasantry as they from time immemorial had heard them from their *runolainen* or singers. An idea of the form and metre of the Kalevala can be obtained from Longfellow's *Hiawatha*, which is an imitation of it. The Kalevala has been translated into many languages and has been favourably compared with the Iliad.

#### Later Finnish Writers

By far the most brilliant of the Finns who wrote in Swedish was J. L. Runeberg (*q.v.*), 1804-77. During the last years of the 19th century there was an ever-increasing literary activity in Finnish, the publication of books in Swedish becoming relatively less. Finland is wonderfully rich in periodicals of all kinds, the publications of the Finnish societies of literature and the sciences and other learned bodies being especially valuable. In imaginative literature there have been several important writers in Finnish, such as Alexis Stenwall ("Kivi"), 1834-72, the son of a village tailor, who was the best poet of his time. The Seven Brothers, an historical romance, is a particular favourite, and he wrote various popular dramas.

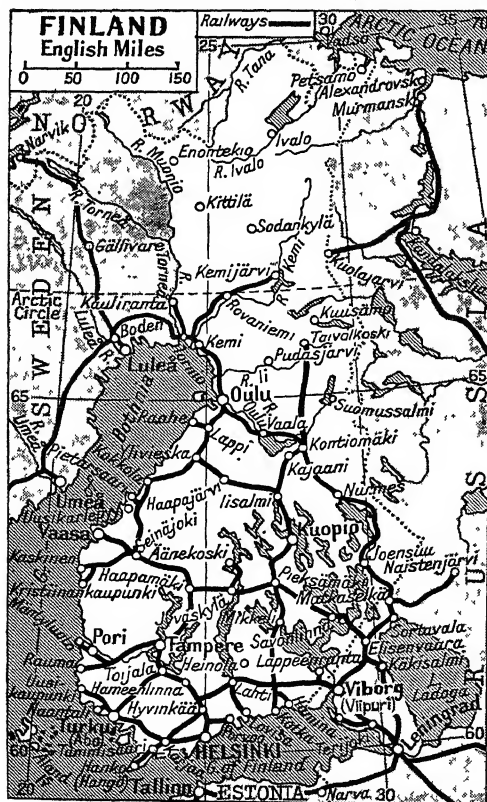

Owing to short or wet summers the country formerly suffered from occasional famines, the last of which was in 1868. These disasters have now been obviated by better means of communications and improved agriculture.

The language is Finnish; but Swedish is understood in the larger towns and is the language of the Åland Islands. It was formerly the official as well as the literary language. The earliest writer in the Finnish vernacular was Michael Agricola (1506-1557), who was bishop of Åbo (now Turku). He published an ABC book in 1544 and a number of religious and educational works. A complete Bible in Finnish was published in Stockholm in 1642.

Finland's earliest novelist was Pietari Päivarinta (b. 1827), the son of a labourer. He wrote the grimly realistic story, *His Life*. The most gifted of writers in Finnish certainly Juhani Aho (b. 1861), the son of a country clergyman. His earliest writings were realistic studies of current life. He went to reside in France, where he made a close study of the methods of French novelists of the newer school. His short stories are delicate works of art, revealing to an interesting degree the temper and ambitions of the contemporary Finnish population.

The only figure of world-wide fame in the arts produced by Finland is Sibelius (*q.v.*)

**HISTORY.** The Finns reached Finland from their Asiatic home in the 7th and 8th centuries; they found people already living there of whom the present-day Lapps are probably the descendants. In the 12th century

Finland. Map of this North European republic, once part of the Russian Empire

Sweden sought to introduce Christianity into Finland, but an obstinate struggle with paganism followed, lasting nearly 150 years. One of the leaders of the first Swedish christianising expedition, Henrik, bishop of Uppsala, an Englishman by birth, later, as Henrik the martyr, became Finland's patron saint. Gradually Swedish influence spread round the coasts and for 600 years Finland formed part of the kingdom of Sweden, enjoying, however, a large measure of self-government. From the beginning of the 17th century the Finns had their own diet, the electoral basis of which remained virtually unchanged until 1906; the system then adopted has survived with a few modifications to the present day. The legal system of the Finnish republic is still based on the *Codex Gustavianus*, maintained over several centuries under Swedish kings, Russian tsars, during the civil war, and since the establishment of an independent Finland.

#### Finland a Theatre of War

Early in the 18th century, Finland became the theatre of bloody struggles between Russians and Swedes. By the treaty of Nystad (1721) Russia secured the province of Viborg (Viipuri). Sweden unsuccessfully tried to recover the lost province in 1741, but the Russian sphere was extended. Finally, in 1809, Sweden withdrew from Finland, the whole of which, with the Åland Is., passed as a grand duchy to Russia, the grand duke being Tsar Alexander I. For many years the relations between Russia and Finland were cordial, and Finland prospered, her autonomy being all but complete save in foreign affairs. Gradually, however, a Finnish national party arose, whose first object was to give Finnish the same standing as Swedish, the then official language of the country. This they succeeded in doing in 1863. In 1899 the Finnish constitution was suspended and Russian military government was established. The assassination of the Russian governor, the dictator, Gen Bobrikov, in 1904, and a general strike led to a temporary respite and in 1906 the constitution was restored. But in 1908 curtailment of Finnish rights began again; but many Finns managed to get through school without learning any Russian, although the teaching of it was compulsory; and in 1914, out of 391 newspapers and periodicals published in Finland,

274 were in Finnish, 103 in Swedish, 7 in Swedish and Finnish, 3 in Russian, 2 in German, 1 in English, and 1 in French.

When, at the outbreak of the First Great War, Russia's coercive measures increased, the Finns, distrustful of Russia's allies, sympathised with the Germans. The Russian revolution of 1917 brought freedom to Finland, which declared itself in Dec. an indepen-

of parachute troops, and for the unexpectedly good defence put up by the Finns. But Finland was overpowered when the Russians, in Feb., 1940, broke the Mannerheim line, and by a treaty of peace concluded in Moscow and ratified by Finland in March operations ceased immediately. The terms included the cession to Russia of the whole of the Karelian Isthmus, the city of Viipuri, the whole

of Viipuri bay with its islands, territory N. and W. of Lake Ladoga, and a number of islands in the Gulf of Finland; both countries pledged themselves to non-aggression; Finland agreed to lease Hanko to Russia for 30 years, with the right to establish a military base there; a new railway was to be built jointly by the two countries to connect Russia and Sweden by a shorter route. The new frontier was approximately that agreed between Sweden and Russia in 1721. Finland lost the port of Viipuri, the defence works of the Mannerheim line, important sawmill, mining,

Finland. A typical Finnish peasant family

dent and sovereign state, and was recognized as such.

In 1920 Finland was admitted to the League of Nations and in the following year she was confirmed in possession of the Åland Is.

**RUSO-FINNISH WARS.** In Oct., 1939, the Finnish and Russian governments began unsuccessful negotiations over the Soviet demand for frontier readjustment and the right to establish air and naval bases on Finnish territory. Next month Russia denounced the Soviet-Finnish pact of non-aggression of 1932, announced the rupture of diplomatic relations, and stated that her only aim was to safeguard the security of the Soviet Union, and in particular of Leningrad (then only 25 m. inside the Russian frontier). Two days later the Russians attacked. A three months' war followed, chiefly remarkable for the use by the Russians for the first time in war

and water power resources, and factories.

When Germany attacked Russia in June, 1941, Finland joined her, and the Finns advanced to their old frontier, forming a constant threat to Leningrad. But the front here remained quiescent until the Russians launched an offensive early in 1944. Then, on June 10, the Russians attacked in the Karelian Isthmus, capturing Viipuri on the 20th. The U.S.A. broke off diplomatic relations with Finland, June 30, and negotiations began, leading to a treaty between the U.S.S.R. and the U.K. on the one hand, and Finland on the other, signed Sept. 19, by which the Finns undertook to disarm all German troops in Finland by Sept. 15, demilitarise the Åland Is., provide the Allies with airfields, return the oblast of Petsamo to the Soviet Union (the Soviet Union renouncing its

rights in the Hanko peninsula), pay an indemnity of 300 million dollars over six years, and restore, subject to certain changes, the terms of the treaty of March, 1940. A German army under Gen. Lothar Rendulic remained in N. Finland, but, cut off from the Gulf of Bothnia, was obliged to retreat through desolate country in the Arctic winter, pursued by the Russians, assisted more and more actively by the Finns as Rendulic left a trail of flaming villages behind him, until on Oct. 25 he crossed the Norwegian frontier, and Finland was freed from war.

**CONSTITUTION.** Finland has a single chamber, the diet or house of representatives, consisting of 200 members elected on a system of proportional representation by all men and women who have reached their 21st year. Women are eligible to sit. The president is elected for six years by an electoral college elected by the citizens. The council of state (ministry) is appointed by the president, but must have the support of the house of representatives. Education has been compulsory from seven to 15 since 1920; 9 p.c. only over 15 are illiterate. There are three universities, one at Helsinki and two (one Finnish, the other Swedish) at Turku. Secondary education is given in lyceums, high and middle schools, there are navigation, commercial, trade, technical, arts and crafts, agricultural, dairy, cattle management, horticultural, and forestry schools. More than 96 p.c. of the population belongs to the Lutheran religion. Among the rest are a few adherents of the Greek Catholic, the R.C., the Jewish, and the Mahomedan religions. Pop. in 1943 was 3,936,178, of whom 1,907,554 were males.

#### Life and Character of the People

The majority of the people are Finno-Ugric, belonging to the great Ural-Altaic family. Physically strong, hardy, and athletic, they have in general round faces, square shoulders, fair hair, and blue eyes. Their temperament is somewhat phlegmatic, and they are honest, hospitable, and clean. They have a keen sense of independence and personal freedom. Since 1920, prohibition of alcoholic liquors has been in force. They live simply and the food of the peasants is poor, but, except in the N. and E., there is little real poverty. The bath-house attached to every farm is characteristic of the country. The Swedish element of the popula-

tion is found in the towns and in the Aaland Is. The organization of public health is well developed.

**INDUSTRIES.** Essentially an agricultural country, with some 60 p.c. of the pop. engaged in this branch, mainly in small holdings of less than 25 acres, only about 3 p.c. of the country is under cultivation; about 5 p.c. is grassland. Oats, barley, rye, and potatoes are the chief crops. A little flax is grown. Numbers of dairy cattle are kept; also sheep, goats, and pigs, while Finnish horses have for long been noted for their speed, hardihood, and docility. Minerals are few and of small importance. Manufactures are well developed, mainly by the help of water power. They include engineering, machine making and shipbuilding, pulp and paper making, production of cotton goods, and tanning. Saw-mills number about 1,000. The chief port is Helsinki, after which come Turku, Kotka, and Oulu. The main exports are timber, butter, paper, pulp, and textiles, while the imports include cereals and other foods, cotton, machinery, and coal. Much of the inland traffic is by water, and so well linked by nature or by canals are the country's many lakes that it is among the countries of the world with the most adequate internal communications. The southern half of the country is well served by railways, of which in all there are some 3,500 m., all but about 150 m. state-owned. They are linked with those of Russia and Sweden.

Wuorinen, 1931; Finland, the New Nation, A. Rothery, 1936.

**Finland, GULF OF.** Eastern arm of the Baltic Sea, between Finland and Estonia S.S.R. Its length is 250 m. and its average breadth 60 m.; it is studded with islands. Several important towns are on the coast—Tallinn, Leningrad, Viipuri (Viborg), Helsinki. On one of the key islands in the Gulf of Finland is the Russian naval base of Kronstadt, which in the Second Great War played a part in the defence of Leningrad and resisted the attacks of German and Finnish forces.

In Oct., 1941, minefields were laid in the Gulf by the Germans and Finns; but Russian submarines and light craft continued to operate in these waters throughout the war, interrupting supply traffic along the coastal roads, sinking enemy shipping, and landing raiding parties behind the front line. When the Russians advanced through Estonia and Latvia in 1944, their warships based on Kronstadt sank many enemy transports in the Gulf and the Baltic Sea. Under the terms of the Russo-Finnish armistice of Sept., the U.S.S.R. acquired the right to establish a naval and air base in the area Porkkala-Udd, a peninsula about 30 m. S.W. of Helsinki. See Baltic Sea; Kronstadt.

**Finlay, ROBERT BANNATYNE FINLAY, 1ST VISCOUNT (1842-1929).** British lawyer, born July 11, 1842. He was educated at Edinburgh university, qualified as a doctor, was called to the bar in 1867, and sat in parliament, where he represented Inverness Burghs, 1885-92 and 1895-1906; Scottish universities, 1910-16. A strong Unionist, he became solicitor-general 1895-1900; attorney-general 1900-06. He was lord chancellor under Lloyd George, 1916-18. Made a viscount, he became British member of the permanent court of arbitration at The Hague in 1920 and the next year a member of the international court of justice. He died March 9, 1929, and was succeeded in the peerage by his son William. The latter, born 1875, became a judge of the high court in 1924 and a lord justice of appeal in 1938; he died June 30, 1945.

**Finlay, GEORGE (1799-1875).** British historian. Born at Faversham, Dec. 21, 1799, he was educated at the universities of Glasgow and Göttingen. He espoused the cause of Greek independence, saw much of Byron at Missolonghi, and finally made Greece his home, never visiting England after 1854. His great work, *A History of Greece from the Conquest by the Romans to the Present Time*, was published complete in 1877, its main parts having appeared in 1844, 1856, and 1861. He died in Athens, Jan. 26, 1875.

**Finmark OR FINNMARK.** Maritime fylke or county of N. Norway. It is bounded N. by the Arctic Ocean and S. by Lapland, and is the northernmost portion of the European land mass, culminating in the North Cape. Area, 18,580½ sq. m. Its rugged coast is indented by bays and fjords

fringed by numerous islands. The surface is elevated, rising to over 3,000 ft. in parts. The climate is severe, and life is hard. Fishing and reindeer breeding are the chief occupations. Hammerfest (*q.v.*) is the chief town. Pop. 53,308, mostly dwelling on or near the coast. Nomad Lapps occupy the interior.

In Oct., 1944, Russian forces pursued the German troops that had retreated from Finland into Finmark. Kirkenes was liberated on Oct. 25. As the Germans retreated, they forcibly removed the inhabitants, destroyed livestock, and burnt the towns of Kirkenes, Hammerfest, Vardö, and Vadsö as well as villages and even isolated farms, leaving the country almost lifeless. Reconstruction began immediately the Norwegian government took charge of the territory.

**Finn**, **FIONN**, **FIND**, OR **FINGAL**. Warrior hero of Celtic tradition. The legends which gather round his name have almost certainly a real historical figure behind them. Finn was the son of Cumhal (*pron. cool*) of Leinster, and was born after his father's death in battle at Cnucha; first called Demne, he came to be called Finn, the Fair One, from his appearance. He took over the leadership of the warrior band known as the Fians or Fianna from his life-long enemy Goll MacMorna. His sons Oisín and Fergus, his grandson Oscar, his herald Ullín, his favourite hound Bran, were famous figures in his story. One of the chief episodes in his career was the pursuit of Diarmid, who eloped with Grania, Finn's betrothed.

In Scottish legends Finn is known as Fingal, and was king of Morven, in Argyll. He was slain in the great defeat of the Fians at Gabra, probably in 283. His memory has never faded among the Gaelic peoples of Ireland and Scotland. See Gaelic Language and Literature; consult also Finn and His Companions, S. J. O'Grady, 1892; Gods and Fighting Men, Lady Gregory, 1910.

**Finnesburg**. THE FIGHT AT. Fragment of heroic Anglo-Saxon poetry, discovered in the binding of a MS. in Lambeth Palace library in the 16th century. It describes incidents of the battle between the Frisian chieftain Finn and the Danes. ~

**Finns**. A name denoting in general a people inhabiting central and northern Russia before the Slavonic dispersion. At first a medium-headed race of hunters and fishers, akin to the tall, blond, blue-eyed Nordic type, they min-

gled in the course of centuries with Alpine rather than Mongolian elements, and are now classifiable mainly by their dialects. These form, with the Ugrian, a branch of the Ural-Altaic family, out of which Aryan probably emerged. Numbering about 6,000,000, they are grouped as Volga, Permian (Votyak), and Baltic Finns. Of the last group the true Finns (Suomi), in Finland and contiguous territories, may exceed 3,000,000. These, having absorbed Swedish influences of race, culture, and speech, display a progressive civilization, a high intellectual attainment, and a passionate love of country. See Finland; Mordvin.

**Finsbury**. London metropolitan borough. Bounded S. by the City, it has the boroughs of Islington on the N., Shoreditch E., and Holborn and St. Pancras W. At one time a manor or lordship, forming one of the prebends of S. Paul's Cathedral, N. of Moorfields, and known as Fensbury, from the swampy nature of the ground, its old fields were practising grounds for military and archers, referred to by Shakespeare and Ben Jonson. Here, in 1548, Protector Somerset was met by the lord mayor on his return from Scotland. Finsbury was once a residential quarter for doctors and surgeons, and it includes Clerkenwell, a clock and watch-making centre. Within its area are Bunhill Fields, Northampton Institute, and St. John's Gate. Finsbury unites with Shoreditch to elect one M.P. Nineteenths of the houses suffered damage from air raids in the Second Great War; about a quarter of the rateable value was lost on Dec. 29-30, 1940. Pop. est. 34,500.

**Finsbury Park**. Recreation ground of N. London, the name of which is applied to the district immediately surrounding it, to an important main line rly. junction, and to a station on the Piccadilly line (for long its terminus). Just outside the county boundary, the park occupies 115 acres between the rly. and the N. continuation of Seven Sisters Road and Green Lanes. It was opened by the metropolitan board of works in

1869, the land costing £56,869 and the laying out about £50,000. It was planned to serve as a public park for the borough of Finsbury, which reached to its S. border.

**Finsen Light**. Form of treatment for lupus and other skin conditions, invented by the Danish scientist Niels Ryberg Finsen (1860-1904). The rays from a powerful electric arc lamp are passed into an absorbent medium which allows only the actinic or chemically active rays to pass through it. These rays, having been concentrated by means of lenses of rock crystal and cooled by being passed through a continuous current of cold water, are directed on to the affected area.

**Finsteraarhorn**. Mt. of Switzerland, between the cantons of Berne and Valais. It is the highest

Finsteraarhorn, Switzerland, and the Aletsch glacier, seen from the air

peak of the Bernese Oberland (alt. 14,025 ft.), and extremely difficult of ascent. The summit was first reached in 1812. The Schreckhorn lies to the N. and the Jungfrau to the W.

**Fin-Whale** OR **FIN-BACK** (*Balaenoptera*). Name sometimes given to the rorqual, a common and widely distributed whale, of which five species are usually recognized. As their yield of blubber is small and their whalebone of inferior quality, they are not in great demand; this doubtless accounts for their being still found in great numbers in nearly every sea except near the Poles. They are of somewhat slender form, and have a short back fin, and narrow and pointed flippers. They have a large pouch in the throat for the reception of the fish on which they feed; and when this pouch is collapsed the skin of the throat lies in a number of longitudinal folds which are characteristic of the genus.

Of the four species included in the British fauna, the common

Fin-whale. Stranded specimen of rorqual, *Balaenoptera musculus*

rorqual (*B. physalus*) is often met with in the English and Irish Channels and cast up on the coasts. Sibbald's rorqual (*B. musculus*) is the largest of all whales, often exceeding 80 ft. in length. It is abundant in the North Sea, and occurs around the Hebrides. Rudolphi's rorqual (*B. borealis*), much smaller, has been found during recent years around E. and S.E. England. The lesser rorqual (*B. acutorostrum*) is about 30 ft. in length, and fairly common around all British coasts. Bryde's whale (*B. brydei*) is found off S. Africa. See Whale.

**Fiord or Ford** (Scand.). Type of inlet found on the coasts of regions which have been greatly glaciated. During the ice age great glaciers scooped out deep trough-like valleys with precipitous sides, and the disappearance of the glaciers admitted the sea. A fiord is usually very deep except near the entrance, and sometimes subsidence of the land has added to its size. Fiords occur in British Columbia, Scotland, and Norway.

**Fir.** Cone-bearing trees of the family Coniferae, and genera *Abies*, *Picea*, and *Pinus*. Natives of Great Britain, N. Europe, N. America, Japan, and the Himalayas, their height varies from 10 to 200 ft. In gardens firs are best grown as specimen trees on lawns, where

Fir. Foliage of silver fir, *Abies pectinata*

silver fir. The genus *Picea* embraces the spruces, and *Pinus* the pines. Their cultivation in large quantities for timber is a branch of forestry (*q.v.*). See illus. p. 1325.

**Firbolg.** Legendary name of an early Irish race, usually said to mean bag-men. Some ethnologists employ it to denote the aboriginal

people, mainly composed of dark-haired, long-headed non-Aryan Iberians, who were subdued by the Milesians, a wave of Goidelic Celts that may have crossed from Great Britain. See Milesian.

**Firdausí** or **Ferdusí** (c. 940-1020). Pen-name of Abú'l Kásim Mansúr, Persian poet, called the Homer of the East. He was born at Schadab, near Tús, Khorassan, son of a small landowner. Carefully educated and an apt scholar, he is famous as the author of the *Sháh-Námeh*, or *Book of Kings*, a metrical history of Persia from early times to A.D. 641; and Yûsuf u Zulikhâ, a poem

on Joseph and Potiphar's wife. The first-named work, in 60,000 couplets, was commissioned by Mahmúd, sultan of Ghazni, who promised 60,000 gold pieces as a reward. Firdausí, however, excited the enmity of Mahmúd's vizier, and when, at the end of his task, which occupied him for 30 years, the vizier sent him pieces of silver instead of gold, the indignant poet divided the money between the keeper of a bath, a sherbet seller, and the vizier's messenger, penned a flaming satire on Mahmúd, and, after spending the remainder of his life a proscribed man, died at Tús. According to legend, as his body was being borne to the grave, a messenger laden with 60,000 gold dinars from Mahmúd arrived, and, as Firdausí's daughter refused the money, it was spent on some much-needed public buildings in Tús.

The *Sháh-Námeh*, which has been described as the *Iliad* of Persia, is characterized by its Persian vocabulary, the simplicity of its style, its high qualities of invention, its original transcripts from nature, its patriotism, its dramatic dialogues, and its reflection of the author's Zoroastrian faith. Battles, combats, feasts, scenes of riot, and carnage alternate with pictures of innocence and peace. Much is taken up with the wars of Persians and Tartars, and one of the central characters is Rustum, the Persian Hercules, who unwittingly kills his own son, an episode familiar to modern readers in Matthew Arnold's poem, *Sohrab and Rustum*.

Zimmern, 1886; *Literary History of Persia*, E. G. Browne, 1902-6; Yûsuf and Zulikhâ, ed. H. Ethé, 1908.

**Fire.** Visible effect of the combustion of substances by means of the chemical combination of atmospheric oxygen with one or more of their constituents. The incombustible residue is called ash. Flame is formed when glowing gas is produced, either as a primary or as a secondary result of the burning. There may also be non-luminous vapours called smoke or fume.

The process of raising the temperature of combustible or inflammable substances to the point at which self-sustaining combustion proceeds is called ignition. This may be brought about by solar radiation, terrestrial heat, molecular action, electrical discharge, friction, pressure, or percussion. Fire may be extinguished before combustion is completed by reducing the temperature of the burning mass below the ignition point, or by stopping the access of air. In the domestic and industrial arts heat and light are commonly obtained from substances—solid, liquid, or gaseous—called fuels, mostly derived from carbonaceous materials of vegetable origin.

#### Early Theories of Combustion

Medieval alchemy pictured the world as composed of four elements: fire, water, earth, and air. When modern chemistry began, Boyle, while still holding fire to be a material element, discovered that air is essential to combustion. A theory propounded by Stahl, that combustible bodies contain a substance called phlogiston, which is released by their decomposition, was not exploded until Lavoisier, after discovering oxygen, explained burning as caused by the extraction of this gas from air and its combination with other substances.

The anthropological theory that early man was a fireless animal is supported by the fact that every primitive mythology has its own account of the origin of fire and of the discovery of its benefits by mankind; in general it is described as a gift of the gods. In Greek mythology, Prometheus brings down a torch lighted at the sun; according to the Vikings, Ukko struck a stone with iron and brought forth lightning; amongst the ancient Egyptians, Phoenicians, and Slavs, there existed fire-gods who personified the diverse functions of fire. The identity between life and fire was an elemental idea amongst the Romans, Persians, Hindus, and Red Indians. The gods of fire possessed variable qualities, *e.g.* the cruelty of Moloch and the beneficence of Hestia.

Traces of fire appear among human relics as far back as early Palaeolithic times. Except the Andaman Islanders, it is doubtful if any race or tribe has been completely without some knowledge of fire. Man's discovery of fire, and his ability to make and use it for his own benefit, marks the dividing line between animal and human existence. Perhaps in the form of burning lava from volcanoes, or from vegetation set on fire by lightning, fire was acquired and preserved for the most primitive use conceivable: for protection from beasts and for elementary cooking. The next stage was the invention of creating fire at will, either by friction of wood, as in the fire drill, saw, or plough, or by the percussion of minerals, as with flints and pyrites.

#### Communal Fires

With the necessity of preserving fire, man became sedentary and was obliged to live in groups; this gave rise to the social instinct, and to the use of fire for warming the person, cooking foods, hardening implements and utensils, and producing artificial light. Hence primitive man found it convenient always to have a fire burning in some protected place, which ultimately developed into a public building round which centred all religious, civil, and political activities. This principle of an ever-burning fire was observed by civilizations as diverse as the Egyptian, Greek, Roman, and Aztec. When the fire of Vesta at Rome went out, all business was suspended until it had been rekindled with appropriate ceremony. No Greek or Roman army would cross a frontier without carrying before it a fire lit from the sacred flame. Fire played a part in the ceremonies observed by ancient and primitive peoples during the initiation of boys into manhood. Most ancient and modern religious beliefs hold that the world will eventually be destroyed by fire.

Uncontrolled fire is the prime destructive agent of man's labours, and throughout history has destroyed more natural and built property than have all the wars combined. Despite the efficiency of modern fire-fighting and prevention methods, fire continues to take heavy toll of life and property; in Great Britain annual losses from fire total £13,000,000 and in the U.S.A. \$85,000,000. Vast tracts of valuable timber are annually lost in the forest fires of Canada and the U.S.A., while bush

fires in Australia, and even heath fires in the U.K., are responsible for much destruction. Most of these fires are caused by spontaneous combustion, but many are the result of carelessness. The wasteful method of clearing scrub land for cultivation by burning the bushes and trees destroys quantities of timber in India.

Sometimes property is fired maliciously, a felony punishable in England as arson and in Scotland as fire-raising. Much evil is wrought by thoughtless or unintentional incendiarism. Out of these perils have arisen the organized services concerned with fire precautions, proofing, prevention, extinction, and insurance.

Two of the most destructive fires of ancient times were those of Rome in A.D. 68, and Alexandria in the 7th century. The Great Fire (*q.v.*) of London in 1666 was one of the greatest conflagrations on record in time of peace. Other destructive fires were at Chicago, 1871; Boston, 1872; Baltimore, 1904; San Francisco, 1906; Yokohama and Tokyo, 1923; Wapping, London, 1935; Marseilles, 1938; Barbican, London, 1939.

The U.S.A., Canada, Australia, and New Zealand have been much more conscious of the dangers of fire, and more advanced in protective measures, than older nations. This is because in new countries buildings were invariably of wood. Many early towns in the New World still contain a high proportion of timber buildings, and in the event of large fires the damage is always serious.

#### Use in Offence and Defence

Like many inventions, fire was turned to warlike purposes soon after man adapted it to his use. In primitive tribal fighting, a prime object was to set alight the enemy's villages. This was achieved by flaming arrows, and, later, by the throwing of pots of incendiary chemicals, *e.g.* Greek fire. Fire later developed into a means of defence, either to delay an enemy's advance or to deny him the fruits of his victory; a notable example was the burning of Moscow by the Russians in 1812. During the Second Great War, the 'scorched earth' policy of the Russians and Germans in retreat hindered the enemy's advance. But fire did not become a controlled and accurate weapon before the development of the flame thrower and incendiary shell, bullet, and bomb in the First and Second Great Wars. (*See* Flame Weapons; Incendiary Weapons.)

It has frequently been used in simpler forms as a political weapon, notably by the Fenians, suffragettes, I.R.A., and I.W.W.

*Bibliography.* Evolution of Culture, A. H. L. Pitt-Rivers, new ed. 1906; The Northward Course of Empire, V. Stefansson, 1922; Man and Culture, Clark Wissler, 1923; Primitive Arts and Crafts, R. U. Sayce, 1933; The Science of Social Development, F. A. Brooke, 1936.

**Fire Alarm.** Mechanical device for making known the fact that a fire has broken out. Fire alarms are of two types, the manual and the automatic. The most common manual fire alarm is the street "break - the - glass - and - pull - the - knob" variety. These alarms are connected to a switchboard in the nearest fire station. When the alarm is pulled, a bell rings in the watch room of the station, and an indicator lights up on the board to show the position of the alarm from which the call comes.

Matter is expanded by heat, and this principle is used in all automatic fire alarms to actuate a mechanism which rings a bell outside the building in which a fire breaks out. The mercurial type consists of a thermometer with platinum wires entering the bulb and the top of the tube through fused joints. When the mercury rises to a certain height it completes the circuit of which the wires form part, and a bell rings. An adjustable form has the top of the tube open and a sliding upper wire.

Pneumatic alarms are operated by the expansion of air in a closed tube or vessel, and the pressing out of a diaphragm which brings a moving contact against a fixed contact. One variety has a bowl-shaped container with a concentrically corrugated top. The chamber is partly exhausted and then sealed. An alarm is given if the air inside be expanded by heat, or the chamber leaks and the vacuum is broken; in either event the diaphragm bulges outwards. In another variety air at atmospheric pressure is contained in a small chamber and in very fine tubes running from it round the walls of the apartments in which it is installed. The air in the tubes is heated quickly by a fire and communicates its pressure to the main chamber.

Metallic fire-alarm contacts employ two metals of unequal expansibility. A common form consists of a bar, compounded of a strip of steel and a strip of copper welded together, or otherwise

rigidly joined, fixed at one end and free to move at the other. When the bar is heated the copper expands more than the steel, and the bar curves towards the steel side, bringing the free end against a contact.

The May-Otway alarm has a horizontal steel bar several feet long, to the ends of which the extremities of a piece of copper wire are fastened. A contact-piece hangs from the centre of the wire. The bar and the wire form together a very obtuse-angled triangle. If the temperatures rise slowly—on a hot day, for example—the steel bar takes in heat as fast as the copper wire and their relative lengths are changed but slightly, whereas a sudden influx of heat affects the wire much more quickly than the bar, and the wire droops sufficiently to let its contact-piece touch a contact below.

Another automatic alarm has a glass bulb filled with liquid in which is trapped a bubble of gas. Increasing heat causes the liquid to expand and shatter the bulb, so releasing a valve, which has been held compressed by the pressure of the air in the bulb. Release of the valve closes an electrical circuit and rings a bell. The bubble of gas in the bulb before it is shattered prevents the alarm from functioning through changes in the weather. Most automatic alarms simultaneously bring into operation a system of chemical or water sprinklers designed to hold the fire in check until the arrival of the fire brigade. (See Fire Prevention.)

It is a criminal offence to give a false alarm of fire to a fire brigade, whether by a street fire alarm or by message. The maximum penalty is a fine of £25 in London and £20 elsewhere.

**Firearms.** Generic designation of weapons which throw a missile by virtue of the propellant power generated by a charge of suitable explosive. While popular use is inclined to restrict the term to such weapons as can conveniently be used by hand, such as rifles, sporting guns, and pistols, these are more correctly termed small-arms (*q.v.*), and firearms includes even the largest artillery.

The history of firearms is, naturally, closely associated with that of explosives, but there is no doubt that in early times progress was far more dependent on the smith than the powder-maker, as the latter was always in a position to supply a more powerful explosive than could be used with safety in contemporary guns. The invention

of firearms is usually ascribed to a German monk, Berthold Schwarz, but the date is not definitely known. From illustrations and accounts in contemporary manuscripts, it is evident that guns were in use by 1320, and the English used them at Crécy, 1346. These were either bottle-shaped or tubular in form, and at first were employed to fire darts with either metal vanes or a leather pad in place of feathers, but spherical shot were early introduced, being usually made of stone, as the guns would not withstand the charge necessary to propel the heavier metal missiles.

The early guns were generally built up of wrought iron strips welded together, but some consisted of wooden staves bound with iron, and all were valued far more for the moral effect occasioned by the noise of their discharge than for the material damage caused. "Hand guns," which appear to have come into use about 1400, were merely smaller sizes of cannon mounted on a rough wooden stock, and all weapons were discharged by applying a piece of smouldering match to the touch hole.

#### *Invention of the Flint Lock*

The next improvement was the invention of the matchlock about 1460, and it was not until the invention of the flint lock early in the 17th century that this was generally superseded. Flint locks remained supreme until early in the 19th century, when percussion caps were introduced. During this time the only improvement in cannon was better construction, they were cast in bronze in the 15th century and in iron by the 18th. The advent of the wheel lock (*q.v.*) in 1515 had also made it possible to produce a practicable pistol, so that three distinct varieties of firearm, cannon, musket, and pistol, were in existence.

In order to increase the accuracy of weapons, rifled barrels were introduced about 1520, probably by August Kottler of Nuremberg, but the slowness of loading from the muzzle end with this type of weapon restricted its use to sporting weapons until the end of the 18th century when a few regiments of marksmen were formed. Not until breechloaders were definitely established did the rifle supersede the musket.

Breechloading guns have been known for some centuries. Henry VIII had a sporting weapon of this type, but the Prussian needle gun of 1841 was the first weapon in which the principle was applied

with any real success. With a view to increasing the rapidity of fire, double-barrel guns were introduced about the middle of the 17th century, magazine rifles about 200 years later, one of the earliest being the Winchester, 1867. Revolvers date from 1835 (Colt).

After 1880 improved construction and the advent of smokeless powder made possible the manufacture of weapons of great power and extreme accuracy; improved breech blocks and the absorption of the recoil by hydraulic buffers revolutionised artillery practice; through the use of the force of the recoil to reload, cock, and fire the weapon, machine-guns were produced which would fire 600 shots per minute.

Developments during the First Great War were in giving mobility to larger guns and howitzers; in the use of guns of immense power as instanced by anti-aircraft artillery and the German gun having a range of 80 miles, which threw 9.1-in. shells, weighing about 3 cwt. each, into Paris; the introduction of new types of ammunition; and the use of trench mortars, which were extremely light cannon, generally smooth-bored and often muzzle-loading, capable of firing heavy projectiles to short and medium ranges. In the Second Great War automatic firearms like the Thompson sub-machine-gun and the Sten carbine were used on a large scale. A further innovation was the rocket gun.

Under the Firearms Act, 1937, no person may normally have in his possession any firearm—except a smooth bore gun with barrel not less than 20 ins. long or an air gun, air rifle, or air pistol of a type not declared specially dangerous by the home secretary—unless he holds a firearms certificate. Such a certificate can be obtained for 5s. from the police, but the applicant must show good cause for having a firearm. A certificate remains in force three years. If the police refuse to grant one, an appeal can be brought to the court of quarter sessions. Among the persons to whom this restriction does not apply are crown servants, persons taking part in theatrical performances or films, starters of races, operators of miniature rifle ranges, and members of rifle clubs and cadet corps. Automatic weapons are forbidden. Firearms dealers must be registered. *See Ammunition; Arquebus; Bullet; Cartridge; Explosives; Machine-Gun; Ordnance; Pistol; Revolver; Rifle; Trench Mortar.*

**Fireback.** Back wall of a fireplace, introduced about the middle of the 16th century as a protection for the walls. Firebacks were of cast iron, often elaborately decorated with designs of flowers, figures, etc., in high or low relief. The most interesting series were those with coats of arms and other heraldic devices, with inscriptions.

**Firebrick.** Term covering all kinds of heat-resisting bricks used in the construction of such appliances as furnaces. Commonly it is restricted to those bricks made from fireclay (*q.v.*), while others are known by the predominant constituent in their composition, *e.g.* as silica-, chrome-, or magnesite-bricks. Pulverised fireclay is mixed with water and pressed into suitable moulds. After shaping, the bricks are slowly dried and finally fired strongly in special brick kilns.

**Fire Brigade.** Organization for combating outbreaks of fire. There apparently existed fire brigades in Egypt 4,000 years ago; an elaborate organization operated in Rome by 40 B.C. Early in the Christian era hose pipes appear to have been in use. For British practice, *see Fire Service.*

**Fireclay.** Material so called from the high refractoriness of the articles made from it, *i.e.* its quality (when manufactured) of resisting intense heat, and its freedom from splitting when exposed to rapid changes of temperature. The determining factor of the refractoriness is the chemical composition of the clay, which contains but small quantities of fluxing impurities (such as iron, lime, magnesia, alkalis), and little free silica. Fireclays should dry and fire without cracking and have an open texture to resist alternate heating and cooling. In the manufacture of some fireclays sawdust is mixed with the clay and is burnt on firing, leaving the open porous texture required. The minimum fusion point for a fireclay is usually taken at about 1,600° C.

Fireclays abound in the British coalfields, underlying or alternating with coal seams. They usually contain 50-70 p.c. silica and 20-30 p.c. alumina, the remainder being iron oxide, lime, magnesia, soda and potash. The beds do not usually exceed 2 ft. in thickness, and the presence of rootlets, coupled with the absence of alkalis, suggests that they represent the soil in which the coal measure forests grew—the plant débris formed the overlying coal seam. Deposits are worked in Cornwall, Devon, Dorset, and elsewhere in

the S. of England. Fireclay from Stourbridge, said to have been worked in the 16th century, is exported in quantity on account of its excellent qualities. *See Brickmaking; Firebrick.*

**Fire Control.** System under which two or more pieces of artillery are ranged or fired on a specific target under the individual command of an officer. During the Second Great War, fire was controlled in field artillery either by an officer in an advanced observation post who transmitted his fire orders to the battery by telephone, or by an observer in an aircraft who was in radio communication with the artillery. Anti-aircraft artillery was controlled by data as to bearing, height, range, and speed of the target set into a predictor (*q.v.*) after the picking up of a target on a radar screen. One master predictor controlled the fire of a number of guns.

In warships, fire was controlled from the citadel or control tower in battleships and cruisers and from the bridge in smaller vessels such as destroyers. From this control position the gunnery officer directed the vessel's guns either from personal observation of the target or from messages received from spotting aircraft. If necessary, the fire control officer could fire all the main armament simultaneously by pressing a switch. The development of radar revolutionised fire control for both land and ship-borne artillery, making it possible to control accurate and sustained fire against a target which might be moving under cover of thick smoke or fog. *See Artillery; Gunnery.*

**FIREDAMP.** The name given to the most important of the gases which are found occluded in the crust of the earth, *viz.* methane, or carburetted hydrogen (CH<sub>4</sub>), which appears in coal mines. When diluted with air in certain proportions it forms a mixture which will explode with great violence when ignited by a flame or spark, or by an incandescent surface. Such an explosion occurring in a coal mine may kill the workers directly by mechanical violence or by burning, or indirectly by carbon monoxide poisoning, since carbon monoxide is formed by the incomplete combustion of the gas.

FIREDAMP and marsh gas have the same composition, and both are formed by the decomposition of vegetable matter. Coal beds are porous and the gas accumulates in their pores, but large volumes sometimes accumulate under con-

siderable pressure in pockets, and when these pockets are tapped by a pick or a drill, or by a fall of coal or rock, the gas escapes into the mine workings and becomes a source of danger. A fall in the barometric pressure tends to release the gas; hence the importance to miners of weather forecasts. The volume of methane is sometimes so great that when a pocket of it is tapped the gas issues in a continuous stream or "blower" for several years. Attention is being given to the possibility of recovering methane (which is used as a fuel in the form of "bottled" gas; see Gas) from such sources. As a natural product of the coal measures, methane occurs in a remarkably pure state, containing less than 3 p.c. of other gases. All mixtures ranging from about 4 p.c. to about 14 p.c. of methane and air are explosive, but, by means of the flame safety lamp, the miner can detect the presence of less than one p.c. of firedamp in the mine air by observing the height of the pale-blue flame of burning methane above the oil flame.

**Fire-eating.** Branch of the juggler's art. It includes exhaling or swallowing flame, holding red-hot iron between the teeth, drinking molten substances, and similar pretensions. A writer of the 2nd century described breathing from the mouth of flame and smoke as arising from inflammable matter inside a nutshell wrapped in tow. In 1672 Evelyn saw Richardson chew and swallow glowing coals and brimstone, besides pouring molten lead—perhaps cold quicksilver—on his tongue. In 1762 Strutt saw Powell broil a piece of beefsteak upon his tongue with glowing charcoal placed beneath it. In 1814 Josephine Girardelli claimed to put molten lead into her mouth and to spit it out marked with her teeth. These effects were produced partly by utilising unfamiliar physical and chemical principles, partly by the performer's sleight of hand.

**Fire Engine.** Machine for extinguishing a conflagration. In 1650, Hautch of Nuremberg made a manually operated fire engine, but it was not very successful. A few years later Jan van der Hydens of Amsterdam invented an improved engine, adding to it later an air vessel and a combined pair of bucket and plunger pumps, the connecting rods to which were attached to a cross lever. The air vessel prevented shock and loss of power, and made it possible for the pumps to give a continuous

stream of water which was delivered through a branch and nozzle fitted to the delivery side of the pump. About 1670 the Dutch invented riveted leather delivery hose. These machines were fed from a cistern which had to be kept filled from buckets.

The first manual engine built in England is credited to Richard Newsham of London about 1724. It incorporated improvements by which water was sucked through a pipe line to feed the pump. A steam fire engine is said to have been made in England in 1829, but not until 1861 was the first horse-drawn steam fire engine adopted by the Metropolitan (London) Fire Brigade. The pump was a single throw piston type fitted horizontally on a carriage, the power to operate the pump being steam generated from a quick heating boiler. Later models had two double acting reciprocating pumps fitted vertically, driven by steam power; forced draught gave sufficient head of steam within 10–15 mins. of lighting the fire under the boiler. Steam propulsion was substituted for horses in 1902, and a year or so later the internal combustion engine superseded steam, a rotary pump being coupled to the driving shaft by means of gearing. The centrifugal pump was introduced in 1906; its impeller shaft was driven by intermediate gearing or belting by any available motive power. Like the subsequently developed reciprocating pump with three throw action, the pistons being in series, it was fitted into a chassis which was either towed behind another vehicle or had its own mechanical propulsion. See Pump.

**Fire Escape.** An appliance to assist the escape of persons who are trapped in a burning building. Fire escapes can be divided into two categories, those owned by the general public, and those owned by a fire brigade. Among the first are: (a) a rope ladder with wooden rungs permanently fixed under the window in a room and generally encased in a box; (b) a reinforced line fitted with a hook at one end to which a sling can be attached, the other end of the line being wound on a drum (with braking device to regulate the speed of the descending person) and enclosed in a metal container with a hook by which to hang it to a permanent fixed ring just inside or outside a window frame; (c) permanently fixed iron or other non-combustible staircase attached to and outside a building, accessible

from each storey by doors opening outwards, and either open or entirely enclosed in brickwork or other non-combustible material; and (d) an entirely enclosed staircase built inside a building as part of its general structure. Enclosed stairway escapes usually have fire-resisting doors on each floor, and are made, as far as is possible, smokeproof. Building by-laws in most cities require the provision of an external fire escape on all buildings having a floor more than 50 ft. above pavement level or occupied by more than 20 persons, and on all factories or workshops employing more than 40 persons.

Portable fire escapes were introduced in 1836, by the Society for Protection of Life from Fire, and were stationed with their attendants in streets of London and other towns. Eventually these escapes were taken over by the fire brigades. They were replaced in time by escapes comprising a series of extending ladders in three sections mounted on a two-wheeled sliding carriage. The ladders were lowered or raised by means of cables and a winch, which was usually mounted between the levers. This type of escape could be propelled by four men; or it could be carried on a fire brigade vehicle and unshipped when required. In cities and large towns fire brigades also have mechanical turntable, self-supporting ladders, some of which can be extended to 150 ft., mounted on a self-propelled vehicle whose engine is geared to a mechanism for extending, lowering, elevating, and rotating the ladders.

In the U.S.A. fire brigades use "aerial" ladders: these, mounted on a turntable swung by hand, and locked by a pin in the desired position, are extended by means of an endless chain and elevated by screw gear, both operations being carried out by hand.

Another fire brigade rescue appliance is the hook ladder, a short light ladder about 16 ft. long fitted with a folding hook, by the use of which firemen can scale a building of any height. These ladders are not intended to be used by persons other than firemen, who with their help fix lifelines to the upper storeys of burning buildings.

**Fire Extinction.** In principle, the limitation of factors causing fire. Such limitation can be effected in various ways, according to the nature of the fire. These include drawing off burning liquid

fuel when stored in tanks, the demolition of adjoining buildings containing combustible materials, the digging of trenches in heath fires, the removal of cargo from ships' holds, smothering to prevent air from feeding the fire. A container of burning oil, for instance, can usually be extinguished by putting an asbestos sheet over it, and at the same time cooling the exterior of the container with water. A person whose clothing is on fire should be made to lie on the ground and wrapped in a heavy rug. In general, water can be used for cooling, but it must not be used in dealing with burning magnesium, certain liquid acids, some alkalis, etc.

**FIRE EXTINGUISHERS.** Apparatus for extinguishing fire is of five types projecting respectively water, foam, vapour forming liquids, dry powders, and emulsions. Soda-acid machines generally consist of a container holding water and bicarbonate of soda with an inner receptacle holding liquid acid; when operated the chemical reaction between soda and acid creates an internal pressure that expels the liquid from the nozzle. In other types, a compressed gas takes the place of the acid; when the inner container is pierced by mechanical means this gas develops pressure in the receptacle, expelling pure water from the nozzle.

The foam hand extinguisher, similar in appearance to the soda-acid type, has separate combined chemical solutions, the inner compartment being charged with aluminium sulphate dissolved in water and the receptacle itself with bicarbonate of soda and saponin, liquorice, or turkey red oil dissolved in water. When operated the appliance projects liquid "foam."

Extinguishers expelling a liquid which vaporises rapidly when in contact with burning material may hold either carbon-tetrachloride or methyl-bromide (both fluids being non-conductors of electricity). Machines containing carbon-tetrachloride can be operated by (a) pump, (b) compressed gas, or (c) air-pressure. In methyl-bromide machines, a total discharge is given by piercing a copper disk with a pin, control discharge by a spring loaded plunger controlled by a trigger, or a wheel valve and cock.

Carbon dioxide ( $\text{CO}_2$ ), compressed into a cylinder in a liquefied state, when released by a valve vaporises; it is a non-conductor of electricity, and is useful for deal-

ing with fire of highly inflammable liquids at any early stage.

Dry powder extinguishers generally consist of finely ground bicarbonate of soda with precipitated chalk, whiting, sand, sawdust, fuller's earth, or dry pulverised clay. Powder extinguishers containing graphite and other finely ground chemicals have been developed to deal with incipient fire in particular materials, but are not suitable for household use. Emulsion extinguishers also are designed chiefly against special fire dangers in industrial premises.

The handpump or stirrup pump may be either single or double acting. The pump is placed in a receptacle containing water, and a length of hose is attached to the pump. Generally two operators are required, whilst a third person is needed to obtain further supplies of water. Garden hose fitted with a nozzle to a water-tap is easier to use. A siphon of soda water is useful for very small fires.

In large buildings and factories with inflammable contents an automatic sprinkler system is common. Piping at ceiling level is installed throughout the building; attached to the piping at equidistant points are sprinkler heads fitted with fusible links which melt at a predetermined temperature, thus opening a valve which emits a continuous spray of water. The area covered by each head depends upon its height above floor level and the pressure under which the water is discharged. The water is supplied by gravitation from a large storage tank in the highest point of the building.

In a building where trained staff are employed, on each floor sometimes stand fire hydrants opened by means of a wheel valve, when the hose and nozzle are connected to the hydrant it is often possible to cover the whole area of the floor. The hydrants are supplied either

by gravitation from a storage tank, or by means of rising mains from street level.

**Firefloat.** Motor vessel equipped for extinguishing dock, riverside, or ship fires or any fire which cannot be reached by wheeled pumps.

A typical firefloat is the Massey Shaw (named after Sir Eyre Massey Shaw, *q.v.*), which is moored in the Thames. She is 78 ft. long and has two stage centrifugal pumps driven by Diesel engines, which also propel the boat at 12 knots. Mounted amidships is a monitor,

Fire Exinction. Left, soda-acid extinguisher: A, steel vessel charged with, B, solution of sodium bicarbonate; C, glass bottle containing sulphuric acid, shattered by striking knob, D; E, jet, connected by tube, F, to base of extinguisher; G, strainer to prevent glass fragments from obstructing jet. Right, foam extinguisher: A, handle; B, nozzle; C, glass container; D, acid

Courtesy of Mather & Platt, Ltd.

or water gun, which can deliver  $1\frac{1}{2}$  tons of water a minute drawn from the river by the pumps. On each side of the deck above the engine room is a swivelling delivery head, each with four hose connexions. At the great Wapping fire in 1935, the Massey Shaw pumped continuously for six days. She was one of the ships sent to Dunkirk to assist in the evacuation of the B.E.F. One of the largest firefloats in the world is the Fire Fighter of New York; she is 134 ft. long, and has nine monitors giving a total water output of 22,000 gallons a minute at a pressure of 150 lb. per sq. inch.

**Firefly.** Name given to luminous beetles of the family Elateridae, found chiefly in the tropics. The glowworm (*q.v.*) is a different kind of beetle belonging to the family Cantharidae.

**Firefly.** Two-seater fighter reconnaissance aeroplane designed by the Fairey Aviation co. for the Royal Navy. It operated from

aircraft carriers. It was powered by the Rolls-Royce Griffon engine, and had a span of 41 ft. 2 ins., length 37 ft. 11 ins. Maximum speed of the Mark IV was 386 m.p.h. Coming into production late in the Second Great War, the Firefly served in all theatres of operations.

**Fire Guard.** Branch of British civil defence in the Second Great War. It was established by an order in council of Aug., 1941, whereby men between 18 and 60 were made liable to compulsory enrolment as fire guards where the Fire Prevention (Business Premises) Order was applied. A month later, all male British subjects between 18 and 60 were obliged to register for fire detection and prevention service. The only civilians excused fire guard duty were members of the Royal Observer Corps, police and special constables, doctors, seamen, and blind and insane persons. In 1942, liability for fire guard service was extended to women between 20-45, and the age limit for men was raised to 63. At the same time members of the Home Guard, part time civil defence personnel, police, and the Royal Observer Corps had to perform a specified number of hours of fire guard service.

Fire guards were given protective helmets and brassards, and were at first linked with the wardens' service, but on Jan. 28, 1943, they became a separate body called the Fire Guard Service, and worked in cooperation with the National Fire Service. Each N.F.S. station area was subdivided into fire guard sectors, each under the control of a Fire Guard section captain, the latter being usually appointed by the local authority. The fire guard sectors were further subdivided into street or block party areas, each with 20-30 fire guards under a party leader.

When the service was suspended on March 24, 1945, it had a strength of nearly 5,000,000 men and women.

**Firelock.** Musket in which the means of igniting gunpowder was by flint and steel. Adopted in England c. 1690, it replaced the matchlock, which required a burning match to discharge it. The drill command "Shoulder your firelock" was used before "Shoulder arms" came into use. It was also known as Flint Lock (*q.v.*).

**Fire-making.** Intentional production of flame, spark, or glowing heat. Of primeval invention, it

became one of the mightiest factors in human culture. Natural manifestations of fire were doubtless feared before man perceived its beneficent possibilities. Use gave rise to preservation, preservation to production at will.

Fire-making may have originated in wood-friction. A Moustertian beechwood fire twirl (Tylor's fire drill) was found in 1904, at Krapina, in Croatia. Fire twirls are rotated between the palms in Australia, as in ancient India and Mexico, are aided by a cord by the Maoris, and by a bow in early Egypt; they are gripped by the teeth by the Eskimo, and weighted with a spindle-whorl by the Chukchi. Other frictional appliances are stick-and-groove fire ploughs rubbed along the grain in Polynesia, and fire saws rubbed across the grain by the Malays. A pneumatic fire piston is peculiar to modern S.E. Asia. The primeval percussion implement—strike-a-light—resulted from flint-knapping, and flint and pyrites developed into the early iron-age flint and steel. *See* Lighter; Match; Tinder-box, etc.

**Fireplace.** Recess in the wall of a room, formerly consisting of an open space walled on three sides by stone or bricks, but now generally fitted with a metal fitting, which contains a fire for space heating. The earliest form of fireplace is commonly believed to have been the hearth in the centre of a room, but there is evidence that the wall fireplace has an equally long ancestry. In the Norman keep, for example, where the rooms were placed one over the other, wall fireplaces were the rule, since a central hearth in any but the topmost room would have been an impossibility.

Extant specimens show that these fireplaces were recesses in the wall surmounted by round arches. There was no chimney shaft; the smoke escaped by a short flue leading almost directly to a small vertical opening in the outside wall, concealed in the angle of a buttress. In one-storeyed buildings the central hearth was often used, and this type of fireplace persisted until late in the 16th century. The great hall at Richmond Palace, and the hall at Penshurst Place, Kent, retain examples.

The opening in the roof, through which the smoke was carried, was protected by a small turret, or *louvre*, which kept out the rain while allowing the smoke to escape. Chimney shafts began to appear about the middle of the

13th century, but were not carried above the level of the eaves until considerably later, and it was not until Elizabethan times that the chimney stack was developed as an architectural feature. Then the number of fireplaces greatly increased, calling for a corresponding enlargement and beautification of stacks to contain the flues (*see* Chimney *illus.*).

Gothic fireplaces are generally treated in the simplest manner. The hood, sometimes with corbels, is the chief and only decoration of most 13th century fireplaces, and the single square-framed arch which followed it was equally devoid of ornament. The Renaissance brought the architectural chimney-piece and elaborate overmantel, and though there was a return to greater simplicity in the Later Renaissance, the taste for a decorated fireplace had taken firm hold. *See* Building; Chimney-piece *illus.*; House.

**Fire Prevention.** Fire prevention begins with the education of the public to avoid acts likely to start fires. Brigade records show that most fires result from the careless use of matches and the discarding of lighted cigarette ends. Fires frequently start in rubbish, which should always be placed in metal containers, and should be periodically cleared from cellars, attics, and other out-of-the-way places, where accumulations of old boxes, furniture, and paper feed a fire once started. Oily rags and certain other sorts of waste material may ignite spontaneously.

Portable stoves and heaters should be placed on non-combustible bases well away from woodwork. Gas rings should be placed on a sheet of metal over a sheet of asbestos if they are used on a wooden table or shelf. A ventilated thimble providing adequate air space between thimble and woodwork should be used when an iron stove pipe passes through a floor or other partition of wood. Gas fires should always be fitted with solid metal piping, and gas rings with flexible metallic tubing with screwed metal connections. The containers of oil stoves should be free from leaks; and oil stoves and lamps should never be filled in the presence of naked lights. Regular cleaning and general overhauling of all these appliances are necessary.

Petrol, benzine, and similar volatile liquids should be handled with great care. It is an extremely dangerous practice to clean clothes

with petrol, etc. The use of naked lights should be prohibited in garages.

Fires in fireplaces should be raked out if the room in which they are burning is to be left empty for any lengthy period. Burning coals should not be moved from one fireplace to another. Hot ashes should be placed in metal dustbins. It is dangerous to pour paraffin from a can on to a sulky fire to make it burn. Tops of ovens and stoves should be kept free from grease, and chimney flues regularly swept.

#### Fire Hazards in the Home

Electric appliances, *e.g.* irons and kettles, should be switched off when not in use, and damaged flexible cord should be renewed. Flexible cord should not be hung on nails or hooks, and it is unwise to fit any paper or fabric shade nearer than two inches to any electric bulb. The fuse is the safety valve of the electrical system, and when blown should not be replaced by a fuse wire giving higher amperage, or by anything except fuse wire.

The unprotected flames of gas or candles should not be placed near windows where curtains can blow on to them. Pendant gas lights require coiling shields. Swinging gas brackets should not be used. Candles should be fitted in proper holders.

All heaters, whether electric, gas, or coal, should be protected by a metal guard, to prevent contact with light fabrics that catch fire easily. Many fires are caused by airing clothes too close to a fire. A naked light should never be used to look for a suspected gas leakage; the main cock at the meter should be turned off and word should be sent to the gas supply office. Heath fires are caused in dry weather by careless picnickers who drop lighted matches and cigarette ends or do not completely extinguish picnic fires.

Dangerous fire hazards in industry include the presence of (a) explosives and compressed "permanent" liquefied and dissolved gases; (b) substances which ignite by the interaction or absorption of moisture and/or air; (c) substances with a flash point below 150° F.; (d) oxidising agents and substances liable to spontaneous combustion and readily combustible solids, such as wood sawdust and shavings, paper, loose fabrics, fibres, and similar materials, and certain finely powdered materials; as well as processes involving the application of

heat, especially with combustible materials, *e.g.* in drying rooms, nitrate salt baths, etc.; the production of inflammable waste or dust; processes associated with spray painting with inflammable or explosive liquids, and the use of inflammable solvents. Managements should adopt all possible precautionary measures to prevent fire, and provide appliances for quelling any outbreak at once. Fire precautions in some factories, such as those manufacturing explosives or celluloid, and those engaged in refining inflammable oils, are prescribed by statutory regulations.

Regulation of fire prevention in Great Britain is, with one or two exceptions, delegated to local authorities, which, either by special acts of parliament or by local by-laws framed under the Local Government Acts, insist on certain precautions being taken against fire in the construction of buildings, *e.g.* as regards construction of flues and hearths. The occupier of premises in which a fire is lit is bound to secure that it does not spread, and is legally liable for the damage if it does. Where a fire starts accidentally, he is not liable unless he has been negligent. The London Building Acts contain provisions designed to give protection against fire. Without the consent of the L.C.C. buildings must not exceed a certain height; warehouses and buildings used for trade or manufacture, if exceeding 250,000 cu. ft., must be divided by walls into divisions not exceeding 250,000 cu. ft.

**Fireproofing.** Misnomer popularly applied to methods designed to render materials or structures fire-resistant. Few materials and no buildings can sustain the application of intense heat for any length of time without suffering some damage. If the fire is hot enough, even steel will melt, and brick and concrete will fuse; there have been fires so hot that the materials of construction have actually flowed.

No method has yet succeeded in rendering any material incombustible; so-called fireproofing merely makes it less inflammable than it was. By means of chemical treatment it is possible so to alter the structure of certain materials that, in the event of their catching fire, they will smoulder or burn away slowly without bursting into flame. Materials thus treated are fire-resistant, as, if flame can be avoided, the risk of a fire spreading is reduced.

Wood may be made fire-resistant by impregnating it with sulphate of zinc and silicate of soda and tungstate. In order that the solution may penetrate the pores of the wood, the air is exhausted from the timber by keeping it under a vacuum for some time before the solution is introduced. In addition to solutions intended to penetrate wood, fire-resistant paints are used for superficial coating. Most of these paints have an asbestos basis, but while imparting a certain fire-resistant property, they are liable to peel off. Two or three applications of lime-wash will also render timber non-inflammable.

#### Fire-resistant Chemicals

Other agents used to render materials less inflammable include common salt, alum, sulphate of ammonia, sulphate of soda, sal ammoniac, borax, sulphate of lime, lime water, ammonium phosphate, ferric sulphate, aluminium hydroxide, and aluminium sulphate. These substances are applied by soaking the material in them in salt solution, and act by depositing minute crystals in the pores of the material. Closing up the pores with a non-inflammable substance denies access of air, so that in the event of fire the material merely chars superficially and does not burst into flame. Aluminium phosphate leaves an earthy deposit, when heated, which covers the material and resists the action of flames, while ammonium phosphate coats the material with a glossy protective covering of phosphoric acid. With most of these substances, it is necessary periodically to renew their application to the material, particularly in the case of fabrics such as are used for theatre curtains, as the crystals are only held mechanically in the pores of the material and repeated movement, gradually shakes them out.

Rendering a building or other structure fire-resistant is a matter of design and selection of materials rather than of so-called fireproofing. The materials which naturally offer most resistance to the action of fire are brickwork, firebrick, terra-cotta, plaster, iron, and steel. Next to good brickwork, reinforced concrete is the best fire-resisting material; it is very strong and takes up less space than brick.

To be classed as fire-resistant, a building should have a steel frame with several inches of concrete or tile covering every single piece of steel, particularly the

beams and columns. No built-in wood of any kind should be used; windows, doors, mouldings, skirtings should all be of metal or other non-inflammable material.

Each storey of the building should be, in effect, separated from those above and below by fire-resistant floors, while each storey should be subdivided by means of fire-resistant doors. It should be possible to close securely all exits from rooms in order to confine the fire, and to seal lift shafts and stairway wells with fire-resisting traps on each floor.

Fire-resisting floors are of various types. Filler-joist floors consist of rolled-steel girders supporting small section "filler" joists, with the panels between the joists and all the steelwork filled in and covered with concrete. Hollow tile floors are made up of clay or terra-cotta tiles or blocks laid in concrete and reinforced with steel rod. Concrete floors are built up concrete laid on steel mesh.

Automatically closing doors are used to isolate any part of a floor on which fire may break out. The doors are usually hung on an overhead track set at a rake so that the door tends to close itself. When open, the door is held by a cord or chain, fixed to the wall by a fusible link, passing over a pulley on the end of the track and carrying a counter-balance weight. In the event of a fire, the heat melts the fusible link, and the weight drops, closing the door. The doors are usually made of two steel plates  $\frac{1}{2}$  in. thick having a core of asbestos. Thermostatically controlled roller doors or shutters are sometimes used in place of sliding doors.

To reduce the risk of window breakage in event of fire, which induces draughts that will fan the flames, fire-resistant glazing, i.e. glass at least  $\frac{1}{4}$  in. thick reinforced by a wire mesh made from metal having a minimum melting point of 1,800° F., is used.

**Fire Raising.** Term used in Scots law for the act of wilfully setting on fire the property of another. The English equivalent is arson (*q.v.*).

**Fire Service.** Body charged with the duty of extinguishing conflagrations. In 1189 the ward-motes of the City of London ordered "all persons who dwell in great houses within the ward to have a ladder or two ready to succour their neighbours in case of fire, and to have in the summer time a barrel full of water for quenching fires." Under Edward I

watchmen were appointed who between sunset and sunrise were to give alarm in case of fire, and some attempt was made to provide organized cooperation, e.g. the city of Worcester in 1467 ordered "bucket carriers to be ready with their horses and buckets to bring water to every citizen when a fire occurred in the city." Failure to do so entailed a fine of forty pence. In 1583 the City of London ordered houses to be pulled down with engines, hooks, and ladders to prevent the spread of fire. (Houses in those days were built of wood.)

By 1774 every fire insurance company maintained its own fire brigade and fire engine, manned by volunteers, who were paid for attending fires on property insured by the particular company. In order that such property could be easily recognized, the company affixed its plate to insured buildings. The London Fire Engine Establishment was formed in 1833. It was supported by the insurance company brigades, an arrangement that continued until 1865, when the Metropolitan Board of Works established the Metropolitan Fire Brigade, under the command of Sir Eyre Massey Shaw. The equipment in 1866 consisted of seven large and 14 small steam fire engines, 64 manual fire engines, and two floating fire engines. In 1889 the Met. Board of Works was superseded by the London County Council, but the brigade changed its name to the London Fire Brigade only in 1904.

The city of New York, U.S.A., had a fire brigade by 1835, since it is recorded that on Dec. 6 of that year "a destructive fire occurred when 600 buildings were entirely destroyed as the firemen were powerless on account of the almost instantaneous freezing of the water in the engines."

Some of the larger cities of the U.K., including Manchester, Liverpool, Salford, Glasgow, and Belfast, were granted special powers by the government between 1845 and 1865 to establish fire brigades.

During 1866 to 1938, various enactments gave local authorities in Great Britain power to establish fire brigades, but did not compel them to do so, and it was usual for the authorities to supply engines and appliances from the rates, but to leave it to volunteers to man them. The Fire Brigades Act of 1938 made it compulsory for all borough, urban, and rural councils to provide both fire appliances and personnel, the costs being borne by the ratepayers,

and to maintain them at a prescribed standard of efficiency.

In 1939 the fire brigades were included in the civil defence forces, and expanded both as to personnel and appliances at the cost of the government. Volunteers, forming the Auxiliary Fire Service, were trained by members of the regular fire brigades. Great Britain and Northern Ireland were divided into areas, and the fire brigades were grouped into districts each with a central control so that they could be mobilised quickly for service wherever needed. During 1940 and 1941, enemy air attacks on cities and towns grew so heavy that there was a grave possibility of breakdown in the fire services; and in May, 1941, the Fire Services (Emergency Provisions) Act was passed. This transferred the control of the fire brigades from local authorities to a central administration, the minister for Civil Defence becoming responsible for the reorganization of the fire brigades into the National Fire Service. This was divided into regions for administrative purposes, and each region was subdivided into fire force areas under fire force commanders. The government bore the cost, except that each borough, urban, and rural council had to contribute annually to the Exchequer 75 p.c. of its pre-war expenditure on its fire brigade. The strength of the N.F.S. in 1942 was approximately 100,000 men and women; 700 were killed in action, and about 7,000 were injured during the war.

The National Fire Service was dissolved by an Act of 1947. Instead of allowing the 1,668 local authorities of the 1938 Act to resume control, however, the Act of 1947 set up 141 local fire authorities under county councils and county boroughs, with four county councils and six district schemes in Scotland. Some central control and direction was retained, and part of the costs of complying with the standard laid down was borne by the Exchequer.

**Fireship.** Wooden vessel filled with combustibles that used to be set on fire and made to drift down upon an enemy fleet when it was at anchor or in harbour. The fireships were sent in thus to create panic or set on fire enemy vessels as they came in contact with them. The coming of steel and steam made the fireship obsolete.

A notable instance of the use of fireships was the attack made by means of them on the French fleet in the Basque Roads on April 11,

1. Headquarters of the London Fire Brigade at Lambeth. 2. Light trailer pump. 3. Fire engine, equipped with turntable ladder. 4. Firemen on extended turntable ladders, dealing with a burning

London store. 5. Fire engine fitted with Diesel compressed-ignition motor pump. 6. Thames fire float, with monitor or water gun mounted amidships, and here at practice. 7. Firefloats at a wharfside blaze.

#### FIRE SERVICE: EQUIPMENT AND ACTIVITIES OF LONDON'S FIREFIGHTERS

1809. At Lord Cochrane's suggestion eight fireships and three explosion vessels, containing 1,400 barrels of powder with 400 shells and thousands of hand-grenades, were sent against the French on a dark night. So great was the panic caused by the explosion of these vessels that most of the French crews cut the cables and allowed their ships to drift ashore. An earlier use of fireships was against the Spanish Armada.

**Fire Step.** Term in military engineering. It is the raised portion of a trench on which a rifleman stands to fire over the parapet or through the sandbagged loopholes.

**Fire Tactics.** Term used for arrangements made to bring hostile troops under effective fire, whether from small arms or artillery. Fire tactics included both the dispositions made of the troops who brought fire to bear and the control by which the fire was directed. Some troops were if possible placed in a position to bring enfilade fire to bear on the enemy, while indirect fire, brought to bear from a position invisible to the enemy, was usually demoralising. Surprise effect was frequently obtained in defence by the withholding of fire by some units until a definite stage had been reached by the attack, and in attack by working some units round to a position in which the enemy did not expect them.

Another form of fire tactics was to site machine-guns in concealed positions covering an area over which an attack was expected; fire was held until the attacking troops had passed, when fire was opened on their rear.

In covering fire used during the Second Great War to enable unsupported infantry to assault an enemy position one Bren gun section compelled the enemy to keep under cover by spraying his position with automatic fire while the riflemen and a second Bren section advanced. The latter section then opened fire while the first advanced. Where no automatic weapons were available, the infantry advanced in waves, one wave giving covering rifle fire while the other advanced.

Fire tactics were also applied to artillery. Thus barrage (*q.v.*) fire saturated the enemy defences, compelling him to keep under cover and cutting his communications with the rear while the infantry advanced to the assault. In counter battery work, the artillery on one side maintained steady fire on the enemy artillery

Fire-Walking. Indian practitioners of the rite, marching over glowing charcoal

and so prevented him from supporting his own infantry. See Artillery; Fire Control; Tactics.

**Fire-Walking.** Magical rite practised by several primitive peoples, mainly to ensure sunshine and bountiful crops. The celebrants walk barefoot over heated stones or embers, and are reputed to emerge unscathed. S. P. Langley, witnessing a ceremony at Tahiti in 1901, found that the volcanic rock used was a bad conductor, the upper surface being only moderately warmed. W. L. Allardyce, watching it in Fiji in 1904, reported that a handkerchief was charred by the stones, and

that a thermometer registered an air temperature over the pit of 280° F. Other modern accounts come from Mauritius, New Zealand, Japan, China, India, and Bulgaria. The rite sometimes consists in passing through flame, especially as an act of devotion, a custom preserved among European rustics when leaping over bonfires "for luck."

Fire-walking as a chastity or sanctity ordeal was recorded in early Vedic India (c. 1200 B.C.), passed into medieval Europe, and in the form of treading barefoot over nine glowing ploughshares was successfully accomplished by Queen Emma, mother of Edward the Confessor. See Ordeal.

**Firewatcher.** Member of a section of the A.R.P. organization during the Second Great War. By a ministry of Home Security order of Sept. 22, 1940, a firewatcher had to be on duty at all times on all premises in which more than 30 persons were employed. The duty of the firewatcher was to deal with any outbreak of fire at the earliest possible moment with the means at his disposal, and also to inform the fire service. Firewatching was suspended March 24, 1945. See Fire Guard

**Fire-Water.** Generic, popular name for any spirituous or distilled liquor, originally used by the natives of half-civilized lands for European cordials. It is akin to the Spanish name for brandy, *aguardiente*, or "burning water," to the Celtic *usquebaugh* and the French *eau-de-vie* or "water of life." See Brandy.

## FIREWORKS: FOR DISPLAY AND WAR

Alan St. H. Brock

*This article, which traces the development of fireworks and explains their composition, is supplemented by shorter ones on the various particular forms of firework, e.g. Rocket; Roman Candle; Squib. See also Flare; Gunpowder*

The art of firework making, or pyrotechny, is of great antiquity and seems to have originated in central Asia, although its subsequent development there has not kept pace with that in the W. A firework may be defined as a case, generally of rolled paper and cylindrical, containing a combination of ingredients capable of burning independently of atmospheric oxygen. To achieve this result one component must possess a supply of oxygen which it gives up readily to the other, or others, during combustion. The first chemical compound used for this purpose was saltpetre (potassium nitrate), which is found in surface deposits throughout Asia; and

the earliest experiments in firework making were probably the result of observing the effect when some saltpetre happened to fall among the ashes of a wood fire, causing the embers to splutter and glow. In course of time, another readily burning ingredient, sulphur, was added, and so the components of gunpowder were brought together. It was not, however, until the 12th century, when the German monk, Berthold Schwartz, invented the principle of the gun, that the most suitable firework composition came to be known as gunpowder.

Firework mixtures seem to have been introduced into Europe by returning crusaders and first

developed in Italy. In 1540, Vanzuzio Biringuccio, of Vienna, produced *De la Pirotechnia*, the first serious work on the subject. By the middle of the 16th century, firework displays of a primitive kind became fairly frequent on the Continent. Stowe records that Henry VIII brought over two Dutchmen, who made hollow shot of cast iron "stuffed with firework or wyld fire," but not until the reign of Elizabeth was anything in the nature of a set display given in Great Britain. In 1572 the Earl of Warwick entertained the queen with a display of fireworks in the Temple Fields. Others given in her honour were at Kenilworth two years later, where "there were fireworks showed upon the water which were both strange and well executed," and at Elvetham, by the Earl of Hertford in 1591.

During the 17th and 18th centuries many displays were given in celebration of coronations, royal weddings, births, peace, etc. The somewhat limited variety of effects it was then possible to produce was supplemented by elaborate scenic structures in the form of classic colonnades and temples, illuminated from within to show transparent pictures. An outstanding example was the "Temple or Machine" erected in Green Park, London, to celebrate the peace of Aix-la-Chapelle, 1749. Over four hundred ft. in length, it was adorned with "frets, gilding, lustres, artificial flowers, inscriptions, statues and allegorical pictures, etc." Fireworks provided one of the principal attractions of such pleasure gardens as Marylebone, Vauxhall, and Ranelagh, which sprang up during the 18th century. At these, more or less elaborate scenic settings provided backgrounds for the pyrotechnic displays. At the end of the century the employment of potassium chlorate enabled colours to be introduced, and, with the increasing variety of effects it was possible to produce, the use of scenic aids gradually declined.

The displays carried out by Brock at the Crystal Palace from 1865 to 1910 and from 1919 until the destruction of the building by fire in 1936 were, perhaps, the most important factor of the development of the art. The peace displays, in Hyde Park, July, 1919, and on the Thames, June, 1946, were highly elaborate and extensive.

**COMPOSITION AND CONSTRUCTION.** Firework compositions always contain an oxygen-supplying

chemical, such as the nitrate or chlorate of potassium, together with burnable substances such as sulphur, and charcoal and carbon compounds such as resins, gums, starch, etc. To these are often added metals either in a pure state finely divided or as salts. Iron and steel filings are introduced to produce sparks and coruscations; powdered magnesium and aluminium give dazzling brilliant flame

candles and rockets. When extra force is required, the case is "choked," either by a diaphragm of clay with a central hole of the requisite size or by constriction before the case is dried.

Tourbillions and Saxons have the ends of the case closed with clay and a horizontal hole bored near either end so that the fire issues at right angles to the axis. The holes in the Tourbillion rotate

the case on a piece of curved wood secured to its centre, and secondary holes pointing downwards project it into the air. The Saxon, or Chinese flyer, revolves on a nail, fixed horizontally, driven through the centre of the case.

Compound fireworks are composed of a number of the foregoing, fixed to wooden frameworks in the form of wheels or geometrical patterns. In the revolving pieces the motive power is supplied by gerbs or turning cases, which are in effect small rockets without heads. The best known pieces are rain-

Fireworks. Various types of fireworks in popular use for displays and illuminations

either with or without sparks. Metal salts, in conjunction with potassium chlorate, produce coloured fires: those of strontium produce red, of sodium yellow, of barium green, and of copper blue.

The usual method of construction is to charge a case of strong paper rolled on a former with the composition. The lower end of the case is closed by constriction or, where necessary, by a diaphragm of compressed clay. The lighting end is "primed" with an easily ignited and hotly burning composition, its function being to start the combustion of the contents of the case. Some types of firework are so designed that the case burns down with the composition; these include coloured lights, starlights, and the small "lances" used to outline designs and set pieces. With others the case remains unburned, and the fire is projected with greater force from the mouth of the case. To this type belong fountains, roman

bow, single and double triangle or caprice wheels, revolving fountains, Saxon cross, chromatrope, and tree piece. The fireworks are connected on the framework with quickmatch—cotton wick soaked in a paste of starch and gunpowder, dried, and threaded in a paper tube. Lancelwork pieces are carried out with small coloured fireworks or lances spaced at short intervals following the lines of a design or picture and connected by quickmatch. The real development of lancelwork, which had hitherto been used merely to outline spokes and scrolls on wheels and for similar purposes, dates from 1875, when portraits and other pictorial effects were introduced in the displays at the Crystal Palace.

Aerial fireworks, such as rockets and shells, are those which produce their effects in the air. Shells are hollow spheres of papier maché filled with stars, or other pyrotechnic effects, and bursting

charge. They are fired from a mortar by means of a lifting charge of gun-power in a conical bag fastened to the lower side of the shell. The quickmatch which lights the lifting charge also ignites a time fuse at the top of the shell, which again ignites the bursting charge and contained effects upon reaching its maximum height.

In addition to their spectacular entertainment value, the uses of fireworks include life saving and communication at sea, by means of line-carrying rockets; distress signals and flares; the destruction of vermin by poisonous smoke emitted by fireworks made for the purpose; "bird scarers" designed to explode at regular intervals; and starters for Diesel engines. In war pyrotechnic signals provide means of recognition and communication, both on land and sea. Rockets emitting coloured stars, Very lights (a development of the roman candle designed to be fired from the barrel of a specially constructed pistol), and bombs discharged from mortars are used. Illuminating flares suspended from parachutes were employed during the Second Great War by the Royal Air Force on night operations. A distress signal, burning with a brilliant red flame and throwing up a succession of red stars, saved the lives of many airmen who had taken to their dinghies after coming down in the sea. Firework mixtures, burned in metal canisters, were also employed to lay smoke screens to conceal troop movements from enemy observation.

**Fire-Worship.** The ritual expression of reverence for fire as a natural element affecting human welfare. It is traceable in Dahomé, among the Ainu, some Mongols, and American Indian tribes. In ancient

Mexico, Xiuhtecutli was revered with daily offerings and periodic rekindlings before his image. The cult prevailed in early Aryan India, whose fire-god Agni, personifying earth-kindled fire, lightning, and solar heat, was reborn daily of ten maidens, the fingers which twirled the sacred fire-drill. Honoured by 200 Vedic hymns, his ritual still survives here and there.

Fire-Worship in ancient Nineveh. Fire-altar and sacrifice from a bas-relief at Kouyunjik, Assyria. Upper picture, fire-altar from Khorsabad, Assyria

In early Persia a less developed fire-worship appears in the Avesta, wherein Atar, a son of Ahuramazda, shares his conflict with darkness and impurity. In the Mazdean ritual, sacred fire, preserved in fire-temples, is not an object of worship but an emblem of divine power. This view is maintained by its modern exponents, the Persian Gabars and the Indian Parsees. At Baku, on the Caspian Sea, 18th century pilgrims gathered for expiation before stone temples near the burning oil wells. Many phases of culture exhibit fire-rituals loosely classed as fire-worship. The perpetual fires of the Greek *prytaneum* and the Roman *regia* with its vestal virgins were forms of Aryan hearth-ritual. These rites survive, with much primitive superstition, among E. European peasantry, and in Damaraland. The Semitic use of perpetual fire-altars for burnt offerings, passed into the ceremonial lights of ritual Christianity. See Moloch; Sun-worship; Zoroastrianism.

**Firing Party.** Squad of soldiers, sailors, or airmen, who fire volleys from small arms at intervals for some special purpose, such as a military execution, or as a

salute at a military funeral. At funerals the firing party marches with the cortège with reversed arms.

**Firing Pin.** Pin that strikes the cap of a cartridge in a rifle or other firearm using cartridge ammunition. In a rifle the firing pin passes through the bolt, and when the bolt is pulled to the rear the firing pin compresses a spring and is held by a sear which engages with a bent. When the bolt is pushed forward to ram the charge into the breech, the firing pin remains to the rear, and is in the cocked position. Upon the trigger being pressed, the sear is disengaged from the firing pin and flies forward to strike the cartridge cap and so fire the round. A similar principle actuates the firing pin of automatic small-arms and machine-guns, except that the bolt is operated by the discharge of the rounds. In the Sten machine carbine the firing pin is fixed to the face of the bolt and has no independent action.

**Firkin.** Old English ale measure, the fourth of a barrel, or 9 galls. Originally it varied from  $7\frac{1}{2}$  to 8 galls., and now it would equal  $9\frac{1}{4}$  imperial galls. As a small wooden cask to hold butter, a firkin contains 56 lb. The word is derived from Dutch *vierde*, fourth, and a diminutive suffix *kin*.

**Fire Beacon.** Eminence in Sussex, England, 3 m. S.E. of Lewes. It rises 718 ft. above sea level and gives views of the English Channel from Newhaven to Seaford, the Weald, and into Kent.

Fire Beacon, Sussex. On the summit is a tumulus broken down by the generations of fires lighted on it

**Firiot** (Four lot). An obsolete Scottish measure of dry capacity, being the fourth part of a boll. It varied for wheat and barley, and in different localities.

**Firm** (Span. *firma*, signature). Word used for an association of business men. In commercial circles of the 17th century and thereabouts it was used for a business signature one that

clinched a deal, and was then applied to the business house that signed. It is now the legal term for members of a partnership (*q.v.*). See Business Names.

**Firmament** (Lat. *firmare*, to make firm). Term used for the vault of the heavens. It is used to translate the Hebrew word *rakia* (Gen. 1, v. 6), which originally meant any-

thing extended or stretched out, and then refers to the universe.

**Firminy.** Town of France. It is in the dept. of Loire, 8 m. S.W. of St. Etienne, and is situated in a coal district which normally employs over 4,000 men. Other industries are steel and iron manufactures, also those of woollens, buttons, and ribbons. Pop. 20,362.

## FIRST AID: HOW TO HELP THE INJURED

H. E. Davison, M.D., Examiner, St. John Ambulance Association

*This article is one of a group that includes Ambulance; Hospital; Red Cross. See also Dressing Station; Medicine; Surgery*

First aid is a term for assistance which may be given in cases of accident or sudden illness before medical advice can be obtained. A knowledge of the principles of first aid has been promulgated widely in Great Britain by the operations of the St. John Ambulance Association; the British Red Cross Society; the St. Andrew's Ambulance Association; and educational authorities. During the two Great Wars, men possessing first aid certificates from any of these associations proved of great value in augmenting the established strength of the Royal Army Medical Corps, and, in civil life, in undertaking stretcher-bearer and dressing-station duty during air raids.

**HAEMORRHAGE AND WOUNDS.** Bleeding demands priority of attention in any accident. It may be stopped by firm and continuous pressure upon the bleeding point, or on the appropriate pressure point in arterial haemorrhage. All dirt, etc., should be removed and the wound be thoroughly cleansed with boiled water and dressed with clean lint, linen, or cotton. Out of doors, a wound should never be bathed unless one can be certain that the water is clean. A handkerchief, if clean, should be applied to the wound, or, if only a soiled handkerchief is available, the inside of an envelope may be placed next to the wound, and the handkerchief used as a bandage.

**FRACTURES.** These should receive attention before any attempt is made to remove the patient from the place of accident. Treatment should be directed towards the immobilisation of the broken bone. Splints consisting of any rigid material, like wood from boxes, stout cardboard, walking sticks, umbrellas, broomsticks etc., should be applied and held in position by extemporised bandages. If practicable the splints should be of such length and so

arranged that the joints above and below the seat of the fracture are kept at rest. In fractures of a bone of one of the limbs, the limb should be gently straightened before the splint is applied, and for the upper limb support should be afforded by a sling.

In dislocations the limb should be placed and supported in the most comfortable position, and cold dressings applied; but otherwise not treated except by a doctor, as by unskilled manipulation grave damage may be done to blood-vessels and nerves in the neighbourhood of the joint.

In sprains a firm bandage should be applied and kept wet by the application of cold water. If the ankle is sprained out of doors the boot should not be removed until the patient returns to his house, as a laced boot acts temporarily as a useful support. Whenever it is doubtful whether the injury sustained is one of sprain or fracture the case should be treated on the assumption that it is a fracture.

**BURNS AND SCALDS.** Treatment should be directed towards the exclusion of air from the injured part. This may be effected most readily by the immersion of the part, if a limb, in warm water in which bicarbonate of soda has been dissolved. The burn or scald should then be dressed as soon as possible with strips of lint, linen, or cotton, covered with some antiseptic ointment, *e.g.* boracic ointment. Any clothing adhering to the burned flesh should be allowed to remain, the remainder of the garment being cut away.

**BITES AND STINGS.** Bites of animals should be cauterised by a liquid caustic, such as pure carbolic acid or caustic potash, but if no such fluid is at hand, a red-hot wire should be used. If there is any suspicion that the animal which has inflicted the injury is mad a doctor should be consulted that treatment for rabies may be

carried out without loss of time. In stings of plants and animals the sting should be removed, the part bathed with weak ammonia, and then dressed with a paste of bicarbonate of soda with water.

**CLOTHING ON FIRE.** The patient should lie down at once on the floor with the flames uppermost. The flames should then be smothered by covering them with any rug, blanket, cushion, or table-cover which may be at hand.

**ASPHYXIATION.** Both apparent drowning and asphyxiation should be treated by the immediate and sustained application of artificial respiration (*q.v.*).

**POISONING.** A message should be sent immediately to the nearest doctor explaining the nature of the case, and, if possible, giving the name of the suspected poison. The bottle or other vessel containing the suspected poison, together with any vomited material, should be kept until it has been examined. Treatment should be directed (1) to the elimination of the poison by the administration of an emetic, except in poisoning by a corrosive fluid, such as oil of vitriol, when the lips, etc., will be found to be burned; (2) towards antagonising the action of the poison by administering the appropriate antidote and giving demulcent drinks; (3) to neutralising the tendency to shock by promoting the warmth of the patient. Emetics readily obtainable are mustard, one tablespoonful in a tumbler of warm water, and salt, one or two tablespoonfuls in a tumbler of warm water. Demulcent drinks are milk, milk beaten up with eggs, cream, and any vegetable or animal oil.

**LOSS OF CONSCIOUSNESS.** All tight clothing should be loosened, and the patient put where he can obtain an ample supply of fresh air. If the face is pale the head should be placed on the ground, and the lower limbs elevated. If the face is flushed, the body should be laid flat on the ground with the head and shoulders slightly raised. In all cases the face should be inclined to one side lest vomiting occur and the vomited matter be sucked into the air-passages. No alcohol, or indeed any other liquid, should be given to an unconscious patient.

**FOREIGN BODIES.** Those in the eye may readily be removed, if on the under surface of an eyelid, by a camel's hair brush, or the moistened corner of a handkerchief. If the foreign body, however, is on the ball of the eye, and not easily removed by gentle brushing, a

drop of almond or castor oil should be dropped into the eye, and a pad of cotton wool bandaged over the eyelid in such a manner that the light pressure of the cotton wool prevents undue movements of the eyeball, until medical advice can be obtained. Foreign bodies in the nose or ear should not be interfered with by the unskilled. No attempt should be made to remove a needle unless a part of it is projecting. The part should be kept at rest, and medical advice sought. Stretchers are necessary in cases of serious illness or of certain accidents out of doors. These may be improvised by removing a door or a field gate from its hinges, or by the use of a ladder.

**REMOVAL OF CLOTHING.** Clothing should always be removed very carefully from an injured limb. It should always be first removed from the sound limb; it may be necessary also to cut away the garment on the injured side. If so, the trousers or coat-sleeve should always be cut up the outer, and not the inner, seam. A boot is best removed by cutting the lace and then the back seam; it will then fall away easily from the foot.

**First Aid Nursing Yeomanry.** Women's voluntary organization founded in 1900 as the Field Ambulance Nursing Yeomanry for service with the British Army in the S. African War. In 1907 the organization was officially recognized by the War Office and its title was changed. The F.A.N.Y. served throughout the First Great War, being one of the first women's organizations to go overseas, where it performed ambulance convoy work and nursing in France, Egypt, and Salonica. The corps subsequently trained as a mechanical transport unit.

Badge of the  
F.A.N.Y.

In 1938 the Army Council invited its cooperation in the formation of the Auxiliary Territorial Service (*q.v.*). The unit now became the Women's Transport Service. It supplied all personnel for the first 10 driver companies of the A.T.S.; these members were called up in Sept., 1939, and went to France and one company to Finland as ambulance drivers. The unit continued to recruit for motor companies of the A.T.S. until Sept. 1, 1941. The remainder of the corps continued as a self-supporting organization with its own headquarters. Its personnel

were employed as drivers (British Red Cross Society); drivers and staff (Air ministry); drivers and canteen workers (Polish forces); telegraphists, coders, and secretaries (special forces); canteen and welfare workers (S.E.A.C. army welfare); and secretaries for the war cabinet, War office, and Foreign office. Some were parachuted into enemy territory; two were awarded the George Cross for work with the resistance movement in France. The peace-time headquarters of the corps is 55, Sloane St., London. S.W.1.

**First Army, British.** Formation of the Second Great War. The so-called "first army" landed in Algeria in Nov., 1942. When it met the Germans in Tunisia on Nov. 16 it consisted of one incomplete infantry division and one tank regiment. The division was completed on Dec. 1; the 6th armoured division was completed on Dec. 15; the 46th division reached the front in the first week of Feb., 1943, the 1st div. by March 22, the 4th div. in the second week of April. During April and May troops from the 8th army who had fought from Alamein were added to the 1st. It was commanded by Lt.-Gen. K. A. N. Anderson, and ceased to exist after fighting ended in N. Africa. (*See* Tunisia, Battle of.)

Canadian, French, and U.S. first armies fought in France and Germany during 1944-45. *See* Europe, Liberation of Western.

**Firstborn.** Technical term in the Jewish religion. In commemoration of the deliverance from Egypt, all firstborn human males were consecrated to God's service, i.e. to the priesthood, but every child that lived more than one month could be redeemed from that service. After the building of the tabernacle the tribe of Levi was appointed to the priesthood in supersession of the firstborn (Ex. 4, 13, 22, 34; Num. 3, 8, 18).

The firstlings of animals, if clean, were offered in sacrifice; if unclean, redeemed. For an ass a lamb had to be substituted, otherwise the neck of the ass had to be broken. The Jews, who are referred to as the firstborn among the nations, still solemnise the redemption of the firstborn on the 30th day after birth. In the N.T. the term firstborn is used in relation to Christ, the dead, and the Church (Col. 1; Heb. 12; Rev. 1). *See* Birthright; Passover.

**First Division.** Legal term. Until the system of divisions was abolished by the Criminal Justice

Act, 1948, the court had power to indicate to some extent the nature of the imprisonment to which a convicted person should be subjected by sentencing him to imprisonment in the first, second, or third division. Even before that Act, the power was rarely exercised and the view is now held that the exact nature of the treatment to be received by persons sent to prison should be determined by the prison commissioners and not by the courts.

Imprisonment in the first division was ordered mainly for persons who could not be regarded as criminals in the ordinary sense of that word; their punishment was mainly confined to loss of liberty. They were not forced to work, although if they did they earned a remission of sentence. They were kept apart from prisoners of other classes and could wear their own clothes and use their own furniture. They could obtain from outside special food and drink.

**First Empire.** Name given in France to the period between 1804 and 1814. In May, 1804, Bonaparte was made emperor, and the first republic came to an end. The empire lasted until Napoleon's abdication in April, 1814. *See* French Revolution; Napoleon.

**First Footing.** New Year's Day folk custom, especially in Scotland and the N. of England. It was regarded as unlucky for a woman or a fair-haired man to be the first visitor to any house on New Year's Day. As soon as midnight chimed people hurried to give their friends first footing, to offer them good wishes, and to partake of their hospitality. The custom may be traced back to Druid times, when the priests sent their young men from house to house bearing branches of mistletoe.

**First Fruits.** Ancient religious practice of offering to God a portion of the first fruits of a crop or the first profits of any commercial undertaking. Prescribed by the law of Moses, among the Hebrews it was usually one-sixtieth, but might be as much as one-fortieth. In the early Christian Church the practice was continued, though it was regarded as a work of devotion and not of obligation. Later it was claimed by the clergy as their due and formed part of their official income. The Apostolic Constitutions (*q.v.*) direct that the first fruits of cattle and crops should go to the clergy, and that other first fruits should be devoted to the relief of widows and orphans. *See* Annates; Tithes.

1. Pressure on the carotid artery, at the point shown, back against the spine, will arrest bleeding from a throat wound. 2. Continuous firm pressure on the femoral artery, about the middle of the groin, may save a patient from bleeding to death from a wound in the thigh. 3. Demonstrator showing how a tourniquet is improvised with a stone, bandages, and a piece of stick

4. Triangular bandage arranged for a large arm sling; the point is taken to the back of the elbow. 5. Finished sling, with point brought forward over the elbow and pinned. 6. Splint improvised from folded newspapers. 7. Fractured jaw secured by two bandages; the four ends are then tied together behind. 8. Improvised splint (broomstick) for fractured thigh. Splints must be well padded when lying against joints

Methods of carrying a patient when a stretcher is not essential. 9. How to make a four-handed seat. 10. Three-handed seat, the right arm of one bearer acting as a back support. 11. Patient being carried on a hand seat. 12. Fore-and-aft method of carrying a patient with a fractured leg

**FIRST AID: EMERGENCY METHODS WHEN EXPERT HELP IS NOT AVAILABLE**

# THE FIRST GREAT WAR, 1914-1918

H. W. WILSON, joint editor of *The Great War*, and GORDON STOWELL

*This is a general survey, designed for ready reference, of the main causes, events, and immediate results of the 1914-1918 world conflict, described throughout this work as the First Great War. More detailed information is given in many other articles, e.g. under the principal battles, Aisne, Marne, Somme, Tannenberg, Verdun, Ypres, Falkland Is., Jutland, etc.; under the histories of the various countries involved; and under such headings as Air Raids; Army, British; Casualty; Compulsory Military Service; Royal Air Force; Royal Navy; Sea Power; Strategy; Tank; War Memorials. See also articles on the various treaties—Brest-Litovsk, St. Germain-en-Laye, Versailles; and biographies of soldiers, sailors, and politicians*

The First Great War was the first war in history in which great nations threw into the scale their total resources of man-power and material wealth, so that the struggle was waged and endured by whole populations rather than only by armies and navies. The opponents were the Central Powers on the one hand, with Germany and Austria as the leaders, and the Allied and Associated Powers on the other, led by France, Russia, Great Britain, and (later) the U.S.A. A list of the combatants is given under Alliance (*q.v.*).

The war began with the declaration of war by Austria upon Serbia, July 28, 1914; and fighting continued until 11 a.m. of Nov. 11, 1918, when it ceased in accordance with the terms of the armistice granted by the Allied c.-in-c. to the defeated army of Germany, the last of the Central Powers left in the field.

## Casualties and Cost

The greater part of the actual fighting was waged by land armies. At the outset the armies of the combatants were mobilised to a total of over 16,000,000 men. At the end of the war the total mobilised strength in service was nearly 26,000,000. From first to last the Germans mobilised 11,000,000; Great Britain and the British Empire, over 9,000,000. Nearly 8 million combatants of all sides were killed.

The material cost of the war can be estimated only approximately. The cost to Great Britain was about £8,000 million; to Germany about the same; to France £5,000 million in addition to the enormous loss by devastation; to Italy £2,400 million; to the U.S.A. £4,200 million. As the immediate or indirect result of the war nearly £40,000,000,000 of expenditure or debt was incurred.

**CAUSES OF THE WAR.** The root causes were implicit in the course of European history during the preceding 50 years: e.g. in the rapid rise of the German empire, the development of a national desire for the ascendancy and dominance of the German race throughout the world, the economic

rivalry with and jealousy of longer-established empires entailed by this desire, and the necessity for an expanding Germany to widen her markets even at the expense of her rivals; in the resentment of France against the harsh treatment she had received after the Franco-Prussian war of 1870, and particularly against the loss of Alsace and Lorraine; in the suspicious antagonism of Russia towards the friendship of Germany for the declining Austro-Hungarian empire; in Austria's mistrust of Russian policy in the Balkans and in the Austrian fear of the aspirations of Serbia, especially after Serbia's victory in the Balkan war of 1912, and in view of her open support by Russia.

## Antagonism in Europe

The effect of these tendencies was to reduce Europe to two mutually hostile armed camps, and the increase on all sides of preparations for war only exacerbated the irritation. Various episodes during the opening decade of the 20th century served to define the precarious situation more clearly. The convention of Algeiras (*q.v.*), 1906, arising out of Germany's challenge to France over her interpretation of the Anglo-French treaty regarding Morocco, found Great Britain strongly supporting France, and led immediately to military conversations between the two countries. In 1908 the sudden annexation by Austria of Bosnia and Herzegovina (mainly because of a fear of the revival of Turkish power in the Balkans after the Young Turks revolution) was distasteful to Russia, and was not recognized by Serbia. The Agadir (*q.v.*) crisis of 1911, following the French occupation of Fez, almost marked a breaking-point, but Germany was not yet ready to counter the additional weight of Great Britain as a potential enemy. The swift increase of the German navy in the year that followed, together with such preparations as the widening of the Kiel canal to admit the passage of modern battleships, were directly aimed at neutralising this additional weight, though these activi-

ties were matched by immediate increases in British naval armament.

But by the summer of 1914, with the Kiel canal ready and Great Britain to all appearance rent by internal quarrels and the threat of civil war in Ireland, Germany no longer felt under the necessity of considering British intervention as a danger to her in case of war.

The personalities of Conrad, at the head of the armies of the Austrian empire, and Berchtold, the Austrian foreign secretary, had a direct influence on the situation, for both were, to say the least, willing to risk a general European war in their fanatical fear and hatred of Serbia and their belief in forceful measures to subdue her before she grew too strong.

The assassination of the archduke Francis Ferdinand, heir to the Austrian throne, together with his morganatic wife, at Serajevo, Bosnia, by a Serbian subject, Prinzip, on June 28, 1914, was seized upon openly by Austria and covertly by Germany as a *casus belli*. The German emperor, William II, was at that time attending the Anglo-German naval manoeuvres in the Kiel canal, but left on receipt of the news, and the manoeuvres were cancelled.

## Austrian Note to Serbia

On July 5 the emperor pressed Austria not to lose a moment which was so favourable to her, and promised to support her in the event of any move by Russia. He gave his opinion that such a move was unlikely as Russia was still unprepared for war and that France, too, would be unable to fight because of her bad financial position and her lack of heavy artillery. To Great Britain he did not allude. On July 5 and 6, after consultation with his military and naval advisers, he decided to make unostentatious preparations for war.

Austria drew up a merciless note to Serbia. It was delivered on July 23 during the period when the French president and premier were at sea, returning from Russia. On July 25 Austria broke off relations with Serbia and ordered 9 corps to

mobilise secretly, when all the ten demands in the note except two, which were referred to The Hague, had been accepted by the Serbian government, and William II himself declared that all ground for war had been removed.

**OPENING OF HOSTILITIES.** To confront Europe with the accomplished fact of war was now the plan of Berlin and Vienna. Francis Joseph was induced by falsehood (Berchtold told him that the Serbs had already opened hostilities) to sign the declaration of war with Serbia on July 28, and next day Belgrade, though an open town, was bombarded by the Austrians. Russia immediately announced (July 29) that a partial mobilisation of the Russian troops required to act against Austria would take place. This mobilisation had begun in secret on July 26, when the tenor of the Austrian note was known, and had proceeded parallel with secret preparations in Germany. Energetic efforts made by Great Britain to refer Austria's quarrel with Serbia to a conference of ambassadors were nullified by Germany.

#### Germany and Russia

On July 29 a German military council met at Potsdam, and the same day the German ambassador at St. Petersburg (Leningrad), then the capital of Russia, threatened Russia with war if she continued her partial mobilisation, which led the Russian staff later in the day secretly to order a general Russian mobilisation. The tsar answered the German threat by proposing that Austria should refer her dispute with Serbia to The Hague, a proposal which was rejected. Bethmann-Hollweg, the German chancellor, on July 29, indicated to Great Britain his intention of violating Belgian neutrality. Russia (at midnight of July 30-31) and Austria (at 1 a.m.) independently decided to proclaim general mobilisations. At noon of July 31, William II yielded to the pressure of the military party in Berlin and proclaimed a state of danger of war, automatically calling out large numbers of reservists. Late that night the German ambassador at St. Petersburg presented an ultimatum to Russia, threatening that Germany would mobilise if Russia did not demobilise in 12 hours. At 3.40 p.m. of Aug. 1, France proclaimed a general mobilisation and, independently of her action, Germany issued a similar proclamation at 5 p.m. At 7.30 p.m. Germany declared war on Russia falsely asserting that her troops had violated German territory.

The Italian government had warned Germany on July 24 that Italy's alliance had ended with the Austrian note to Serbia, and on July 31 it informed France that it would remain neutral. Great Britain, in the night of July 26, had ordered the fleet not to demobilise after the test mobilisation just carried out, and on July 29 the First Fleet left for Scotland to take up its war position.

#### German Moves to the West

At 8 p.m. of Aug. 1, German troops violated the neutrality of Luxemburg (an act of war, as this neutrality was guaranteed by France and Britain), and next day occupied Luxemburg and violated the French frontier at many points under orders from the staff. At 7 p.m. of Aug. 2, Germany delivered to Belgium her ultimatum, which had been prepared on July 26, and sent under seal to Brussels on July 29. It demanded within 12 hours permission to move German troops through Belgium on the false pretext that the French meditated an invasion of Belgian territory. At 6.45 p.m. of Aug. 3 the German government declared war on France.

Early on Aug. 4 the British government presented an ultimatum to Germany, requiring her before midnight to pledge her respect for Belgian neutrality. Bethmann-Hollweg replied that Belgian neutrality had already been violated by German forces, and complained that, "just for a word, neutrality, just for a scrap of paper, Britain was going to make war on a kindred nation." At midnight German time (11 p.m. of Aug. 4, British time), war began between Britain and Germany.

**W. FRONT—OPENING PHASE.** The German plan, in pursuit of which war was begun and Belgium invaded, was as follows: One German army (4 corps) was left in the E. to protect E. Prussia and co-operate with the Austrian forces, 600,000 strong, which were to attack Russian Poland. Austria was to move part of the armies, 500,000 strong, which she had directed against Serbia, back from the Serbian frontier to act against Russia. The main German strength was to be flung upon France and Belgium to annihilate the French armies before they could complete their mobilisation, and to reach Paris by a swift advance.

Behind this great advance reserve troops were to seize the Channel ports to prevent a British disembarkation, if the British did not act at once. To prepare for this move-

ment a German advance army was to enter Belgium and seize the junction and fortress of Liège. The Germans expected no serious resistance from Belgium, and after crushing France and dictating peace, intended to transfer the bulk of their army to the E., and then to force Russia to conclude peace. The Belgian resistance and the Russian advance into E. Prussia shattered this plan; 3 corps were detained in Belgium and at Maubeuge and 2 corps had to be sent to E. Prussia; and the absence of these corps brought the German defeat on the Marne. The German advance through Belgium was marked by many incidents of ruthless and savage cruelty towards the civilian population, which aroused the horror of the civilized world. (*See Belgium: History.*)

The French in their plans wrongly assumed that no great advance would be attempted by the Germans in W. Belgium; and that the German reserve divisions and corps would not be employed in the main attack.

As the result the Germans were able to place 1,750,000 well-equipped troops in line against French effectives of about 1,200,000 and completely to outflank the French. Yet in the French dépôts there were 1,000,000 reservists without arms or equipment.

#### B.E.F. in France

While the British expeditionary force of two corps assembled at Maubeuge, five French armies were concentrated from Mézières to Belfort. This disposition left over 100 m. of the N. frontier of France unguarded and gave no aid to Belgium.

British sea-power asserted itself at the outset, enabling the two British corps to move to France and take their place in the French line. As no aid was given to the Belgians, the Germans advanced rapidly, taking Liège and Namur. The Germans passed S. of the Belgian forces, brushing them back on Antwerp, and then swept W., moving on Brussels and Valenciennes. Other German armies passed through the Ardennes.

The principal mass of the German armies turned both flanks of the British and the 5th French army and menaced them with envelopment. They detected the German intentions and eluded the blow by swift retreat. The respite gained by this retreat of 130 m. was used to rearrange the French commands and dispositions.

Joffre, the French c.-in-c., found himself too weak to fight on

the Somme, and a further retirement was ordered. The retreat to S. of the Marne lengthened the German line of communications, exhausted the troops, and gained time for Allied reinforcements to arrive. The French government withdrew to Bordeaux on Sept. 2.

Kluck with the 1st German army had orders to protect the German right and the exposed flank of Bulow's 2nd army. On Aug. 31 in response to directions from Bulow, he began to move S.E. across the Paris front in order to aid Bulow. This movement was approved by Moltke, the German chief of staff; the British were assumed to be out of action. The German cavalry reached Ypres, Lille, Arras, and Chantilly. On Sept. 2 the German command ordered Kluck to échelon his troops behind the 2nd army. He disobeyed and continued his inward movement so as to carry out the general object, which was "to drive the French S.E. from Paris." Gallieni, the governor of Paris, detected Kluck's movement; on Sept. 4 he began to reinforce the French army N.E. of Paris with troops from the Paris garrison. Orders were issued for the general attack on the Germans which brought the first battle of the Marne (*q.v.*).

**E. FRONT—OPENING PHASE.** The German plan in the east provided for an advance into Russia, assuming that the Russian army would not be able to act for two months and trusting Austrian assertions that the Austrian forces were superior to the Russians. The Austrian staff committed the mistake of striking at once with almost equal forces on two different fronts—against Serbia and Russia. The Germans were disagreeably surprised by the rapid advance of the 1st (Rennenkampf) and 2nd (Samsonov) Russian armies into E. Prussia, though Samsonov's force had not been properly mobilised, and the movement was undertaken with grave misgivings at the request of France.

#### Battle of Tannenberg

Rennenkampf drove back the German front in a sanguinary battle at Gumbinnen (Aug. 18–20) and moved towards Königsberg, but very slowly. Samsonov, advancing with five ill-equipped corps to the S. of Rennenkampf, was attacked by Hindenburg at Tannenberg; he was killed, while the greater part of his army was destroyed because of Rennenkampf's failure to support him. The Germans turned on Rennenkampf, who escaped with heavy loss by a hasty

retreat. But this campaign, despite its disasters, forced the German staff to send two corps E. on the eve of the Marne, and took pressure off the French.

The Austrian operations were marked by utter failure. Part of the Austrian 2nd army was recalled from Serbia on Aug. 18 to assist in protecting Lemberg (Lwow), but it arrived too late. The 1st and 4th armies, advancing into Poland, gained small successes. While they were moving N. two other Russian armies, 3rd (Rusky) and 8th (Brusilov), struck at Lemberg, forced the Austrians defending that place to give battle in unfavourable conditions, and on Sept. 3 took Lemberg. The Austrians in Poland had to retire. On Sept. 6 another battle opened at Rava Russka which closed with a fresh Austrian retreat and with the loss to the Russians of all E. Galicia.

The Russians advanced towards Cracow, after taking Jaroslav (Sept. 21) and investing Przemyśl (Sept. 24); at the same time they seized the Dukla Pass in the Carpathians. Falkenhayn, who had succeeded Moltke as chief of the German staff after the Marne, fearing an Austrian collapse and the loss of Silesia (vital to the German munition industry), determined to attempt an offensive in Poland under Hindenburg, in cooperation with the shaken Austrian forces, but had to retreat (Oct. 27).

#### Struggle before Warsaw

On Nov. 4 the investment of Przemyśl was renewed, and Russian cavalry entered Silesia. Once more the plight of Austria became desperate, and, to save her, Hindenburg struck at the Russian right flank and captured Lodz, while the Russians were also checked by the Austrians before Cracow and compelled to retire towards Warsaw, before which city a fierce struggle began (Dec. 7). In Feb., 1915, the Russian 10th army suffered a repitition of Tannenberg at Augustovo, losing 100,000 men; but, as an offset to this, the Germans were repulsed at Warsaw.

On the Serbian front the Austrian operations in 1914 were disastrous. Shabatz was occupied on Aug. 16, and an advance begun on Valievo; but the Serbians attacked (Aug. 17) and completely defeated their opponents. The Austrians retreated, evacuating Serbia, but began another offensive (Sept. 8), when they were again defeated. A third Austrian offensive opened in Nov., and issued in a fresh defeat at Mt. Rudnik (Dec. 8).

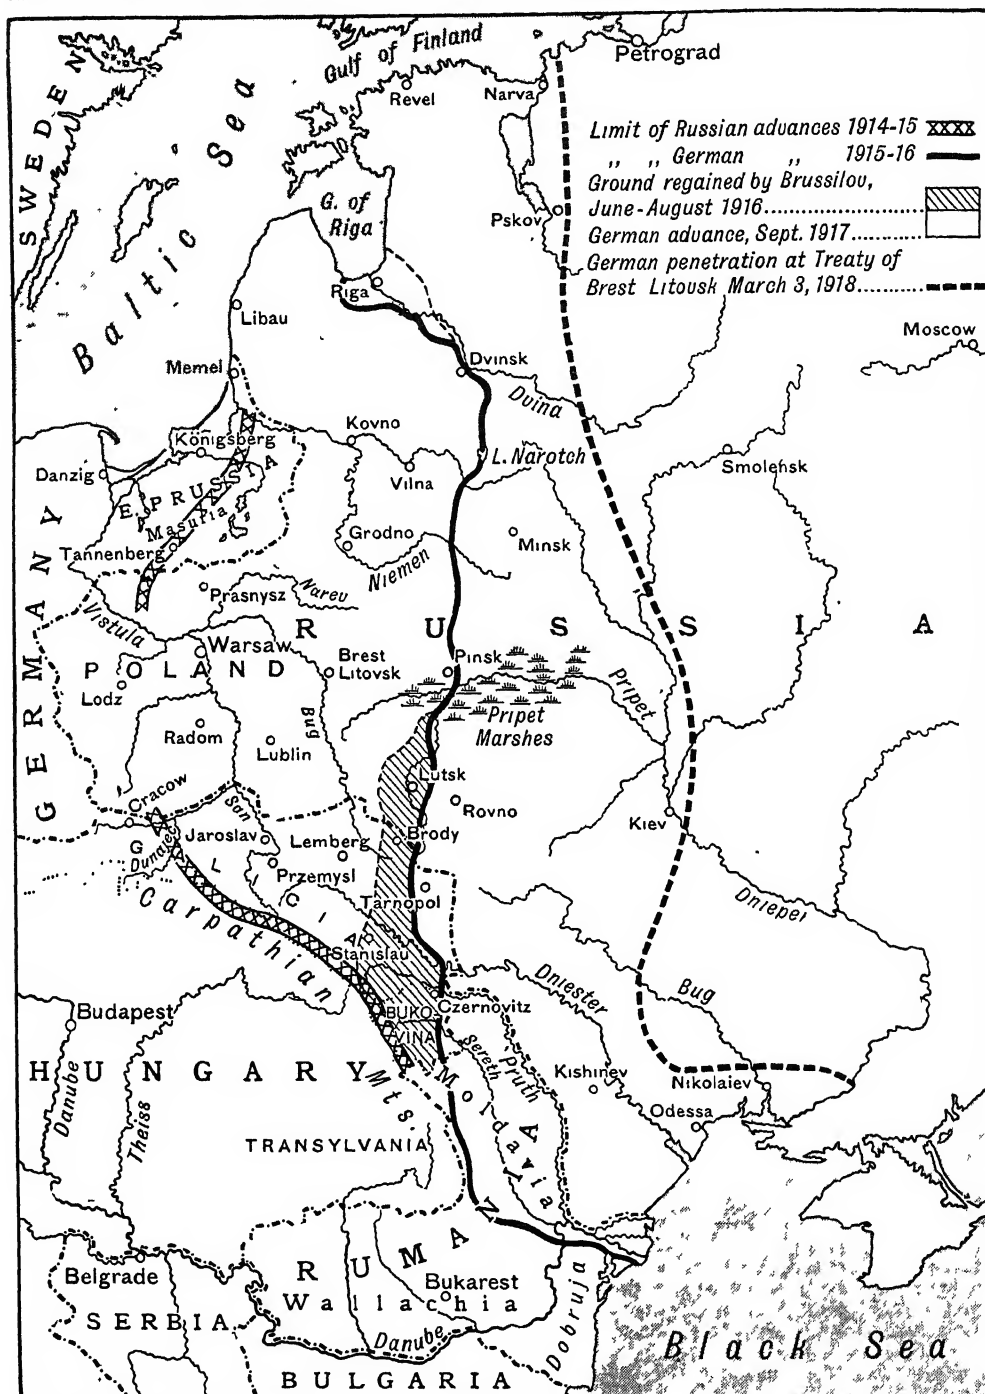

**TRENCH WARFARE IN THE W.** Beaten, but not by any means routed, on the Marne, the Germans fell back on positions N. of the Aisne, which they fortified and held for nearly four years, and trench warfare began on this section of front, after the failure of the Allies in a frontal attack to make any impression. The French command endeavoured to outflank the Germans to the W. in the "race to the sea," and thus to relieve Antwerp, but it was gravely handicapped by shortage of munitions which paralysed its efforts. The British force was moved (Oct. 3–19) from the Aisne to Flanders, a necessary consequence of the decision to raise a large British army.

#### Fall of Antwerp

Meantime, Antwerp fell (Oct. 9), and the German staff also made a determined attempt to outflank the Allies; it extended its right and strongly reinforced it with new corps, secretly raised and trained. The British 7th division landed at Zeebrugge in early Oct., but, unable to advance in face of large German forces, it entrenched at Ypres, and there bore the first shock of a violent German attack, which it beat off with a loss of 75 p.c. of its own strength. As the Germans maintained their pressure at Ypres, more British troops, with a number of French divisions, were brought up. The battle raged along the Allied left from the sea and Ypres as far S. as Armentières, and ended on Nov. 11 in deadlock. The Germans secured Zeebrugge and Ostend, but were prevented from seizing Calais and Boulogne.

The front in the W. now extended 500 m. from the sea to Switzerland, so that it could not be turned at either extremity. This conditioned to indecisive battles until one side or other could obtain marked numerical superiority and the means of attacking machine-gun positions. The tactics of a breakthrough had to be worked out by experiment. In both Germany and France the manufacture of munitions (*q.v.*) was being pushed on a gigantic scale, but not until May, 1915, did Britain take adequate steps.

Allied attacks in the W. at Neuve Chapelle (March 10, 1915), Aubers and Festubert (May 9–16), Arras and the Champagne front, in the winter and spring, brought terrible casualties with the most trifling gain of ground. The British offensives proved that without something like unlimited supplies of high-explosive shells little could be achieved against

It should be noted that the lines on this map of the operations in the eastern area do not in most instances represent continuous battle fronts. For one thing, the trench system was never so highly developed as in the west, for another, they are intended to show limits of advance or retreat that were not necessarily contemporaneous. For instance, the advance of the Russians in E. Prussia in 1914 had been broken at Tannenberg before their maximum advance in Galicia was attained. Place names and boundaries shown here are those recognized 1914-18.

FIRST GREAT WAR: MAP SHOWING CAMPAIGNS ON THE EASTERN FRONT

the mass of German machine-guns mounted behind steel or concrete. The need to speed up production of shells led to the formation of a vigorous ministry of Munitions under D. Lloyd George.

In this period of preparation the Germans made a great attack at Ypres (April 18–May 24, 1915), memorable for the first use by them on the W. front of gas emitted from cylinders (they had already used gas shells before Warsaw with deadly effect). But for the magnificent heroism of the Canadian troops Ypres would have been lost. In the autumn a joint offensive had to be opened prematurely by the British (Loos, Sept. 25) in cooperation with the French (Arras and Champagne), with the object of relieving Russia. The gains were small, and the German front remained unbroken at the close of the year.

**OTHER FRONTS.** On the outbreak of war the German battle cruiser Goeben (*q.v.*) and light cruiser Breslau (*q.v.*), under Admiral Souchon, escaped up the Dardanelles, in violation of treaties and with the connivance of the Young Turks, who had concluded a secret alliance with Germany (Aug. 2). The defeats of the Germans and Austrians on the Marne and at Lemberg caused some hesitation on the part of the Turks, but on Oct. 29 Turkish torpedo craft bombarded Odessa without declaration and Turkey entered the war. As it was vital to protect the oilfields in W. Persia, from which the British navy obtained a large part of its fuel, a small British-Indian force landed at the head of the Persian Gulf (Nov. 21) and secured control of the Euphrates delta. The Turks attacked Russia in the Caucasus, but were defeated with a loss of 75,000 at Sarikamish (Dec. 25–28) and Kara Urgan (Jan. 10–16, 1915).

#### Gallipoli Campaign

These battles diverted Russian troops and munitions from Europe, and led the Russian government to appeal to Britain for a demonstration against the Turks. Such was the beginning of the ill-fated Gallipoli campaign, and of the dispersal of Allied forces in secondary areas. The naval attack on Turkish fortresses commanding the Dardanelles began Feb. 19 and continued until March 18. British and French troops landed on the Gallipoli peninsula on April 25. The campaign achieved nothing and the peninsula was evacuated Jan. 8–9, 1916. (*See* Dardanelles; Gallipoli.)

On May 23, 1915, Italy declared war on Austria, but her army was hampered by bad weather and want of munitions. Her forces did not press forward through the valleys, but attacked in the mountains on a narrow front, and made but insignificant progress. Yet Italy's action, coming at a moment when Russia was succumbing to defeat, diverted the attention of half a million Austrian troops. In the spring of 1915 eight fresh German divisions were sent to the E. with the object of attempting to break through the Russian front near its centre on the Dunajec and at Gorlice.

#### Allied Disasters of 1915

On Mar. 22 the Russian armies in Galicia reached the high-water mark of their advance with the capture of Przemyśl. Unfortunately, a whole Russian corps was being held ready to move against Constantinople in cooperation with the Allies at Gallipoli. A month later Hindenburg was ready. His subordinate Mackensen broke through the Russian front (April 28–May 2) at the chosen point, by means of an overwhelming artillery barrage. The Russians had neglected precautions and had no rear positions; that they escaped complete disaster was due to defective German strategy. The Germans took Warsaw (Aug. 5) and the Polish fortresses, overran all Poland, and pressed the Russians back to a line which ran from W. of Riga through Dvinsk to Tarnopol. In July, 1915, the German government attempted to induce the tsar to make peace, but the offer was rejected.

These disasters were followed by the overrunning of Serbia, in which Bulgaria joined. The Bulgarian government had signed (Sept. 6, 1915) a secret treaty of alliance with Germany, pledging itself to attack Serbia not later than Oct. 11.

**THE WAR AT SEA.** At the opening of the sea-war, the flow of supplies to Germany was somewhat impeded by the British cruisers; but as Germany had prepared for only a short conflict, the failure to institute a complete blockade was a grave mistake on the Allies' part. No such compunction was shown by the German cruisers. The German main fleet virtually withdrew from the war, leaving its submarines to prosecute a policy of attrition, but an almost "watertight" blockade of Russia was carried out by the Germans in the Baltic and the Turks in the Black Sea, with disastrous results to the Allies.

From time to time the Bight of Heligoland was swept by the British navy, and on Aug. 28, 1914, 3 German light cruisers and 1 destroyer were caught and sunk. After a period of inaction the German battle cruisers attempted a series of raids on the British E. coast, shelling Yarmouth at long range (Nov. 3, 1914), and Hartlepool, Whitby, and Scarborough (Dec. 16) on which occasion part of the British fleet had a narrow escape from the whole German force. On Jan. 24, 1915, the German battle cruisers were caught in the North Sea on the Dogger Bank (*q.v.*), and the Blücher was sunk.

German cruiser operations at the outset caused serious loss to British shipping. The only considerable German squadron at large in Aug., 1914, was von Spee's force on the China station, which included two good armoured cruisers. These sailed to S. America and off the Chilean coast destroyed Cradock's weak British squadron at Coronel (Nov. 1, 1914), but on Dec. 8 were caught by a powerful British force off the Falklands (*q.v.*) and destroyed.

Under the rules of the Declaration of London, 1909, almost all commodities vital to Germany could pass through the British cruiser lines; this Declaration had to be modified repeatedly, but it was not abandoned till July, 1916. From Feb. 18, 1915, the Germans proclaimed a submarine blockade of Britain; all vessels, including even neutrals, were liable to be sunk in a "barred zone" round the British Isles.

#### British Blockade of Germany

The British government, as a "retaliatory measure" declared (March 1) that it would prevent commodities of any kind from entering or leaving Germany. But owing to fear of neutrals, especially the U.S.A., large quantities of supplies were permitted to reach Germany. The blockade did not become watertight until 1917, after the U.S.A. had entered the war. Thus, for the first 2½ years, Germany was not subjected to the pressure which the supreme naval power, Great Britain, might have exerted.

Throughout the war the German batteries on the Belgian coast were bombarded with little result. At the Dardanelles, forts once more proved their superiority over ships. In the Black Sea and Baltic there was continual skirmishing; the Russian fleet in the Baltic acted as a drag on the activity of the German fleet and was a perpetual

menace to N. Germany. British submarines entered that sea and inflicted some loss on the Germans, though attacks on the Pommern and Moltke, which were both hit by torpedoes, did not succeed in sinking them. In the Adriatic the Austrian fleet bombarded Italy.

In 1915 the most memorable event at sea was the sinking of the *Lusitania* (*q.v.*), May 7. In 1916, the German commerce-destroyer, *Moewe*, which had escaped in 1915, inflicted considerable damage on Allied shipping. Lowestoft was bombarded by the German battle cruisers (Apr. 25), but only trifling damage was done. This affair was intended to support the Sinn Féin insurrection in Ireland which broke out on Apr. 24. The German fleet was caught at sea (May 31), and the battle of Jutland (*q.v.*) was fought with indecisive result, the Germans escaping after inflicting far heavier loss than they sustained, though they were much inferior in strength.

**WESTERN FRONT, 1916.** At the close of 1915 the German staff decided to anticipate an Allied offensive in the W. by an attack on Verdun. This struggle for Verdun, in which the determined, ruthless onslaughts of the Germans and the epic heroism of the French were each far in excess of the worth of the position to either side, especially in view of the very heavy casualties (over 300,000 on either side), opened on Feb. 21, 1916, and was not abandoned until the following December. (*See Verdun.*)

#### First Somme Battle

A joint Anglo-French offensive had been planned for the close of the summer of 1916. Haig, the British c.-in-c., favoured attack on the Yser near Ypres, where the Germans could not have fallen back without abandoning their bases on the Belgian coast. Difficulties of terrain and of co-operation with the French prevented this. It was then determined (Feb. 18) that a great attack should be delivered on both banks of the Somme. The British army was in a better position to carry out such a plan because (May, 1916), after many hesitations, the British government had imposed compulsory military service for the first time since 1815.

The attack had to be delivered earlier than had been intended, in order to relieve the French at Verdun; and the French force had to be reduced owing to the large number of men absorbed at Verdun. Opening on July 1 on a

20-mile front, it resolved itself into a series of assaults on fortified villages, each of great strength. The moral effect was marked; Falkenhayn was removed and replaced as chief of staff by Hindenburg (Aug. 29). But with continuous rain the Somme battlefield gradually became a morass. The tanks, a British invention, making their first appearance in small force with untrained crews (Sept. 15), disappointed hopes, partly because their tactics had not been worked out, partly because the terrain was unfavourable, and partly because the high command did not immediately appreciate the potentiality of the new weapon. (*See Somme; Tank.*)

**E. FRONTS in 1916.** Contrary to German wishes and without previously informing the German command, the Austrians opened a great offensive from the Trentino (May 15, 1916), advanced to Asiago, and threatened the whole Italian position in Venetia. Brusilov, commanding a group of Russian armies, opened fire on a front of 200 m. (May 31); on June 4 his infantry assaulted and broke into the Austrian front, compelling the recall of troops and guns from Italy. The Italians, when the Austrians weakened in their front, captured Gorizia (Aug. 9).

With furious energy Hindenburg reorganized the German armies and hurried reinforcements to the E. to support the demoralised Austrians, who were surrendering by the thousand. The "elastic system," or defence in depth, was ordered on the Somme, by which the Germans were to fall back slowly after inflicting the maximum of loss on the British. Brusilov entered Stanişlau (Aug. 10), but already the discipline of his troops was failing; ammunition was running low; and German troops were arriving and entrenching strongly. His advance died away, after he had taken 350,000 prisoners.

#### Rumania Joins the Allies

Rumania at this juncture joined the Allies—too late. Her army, formidable on paper, lacked modern equipment and munitions. She had hesitated for many reasons—because she distrusted Russia, because her claims conflicted with those of Serbia, and because the Allies objected to her proposed strategy. The Russians wished Rumania to deliver the main attack on Bulgaria with the support of the large Allied army at Salonica. Rumania preferred to occupy Transylvania and called for an Allied offensive from Salon-

ica before she moved. This offensive Sarraïl, the Allied commander, was unwilling to promise, so long as Constantine of Greece threatened his rear. On Aug. 17, 1916, Rumania signed a military convention with the Allies by which she was to enter the war on Aug. 27–28. The Allies were unable to make any considerable advance from Salonica. All that was effected was the recovery of Monastir by the Serbians (Nov. 19), who had now re-entered the field. The Rumanians were quickly brought to a standstill in Transylvania. Bukarest fell (Dec. 6) and Wallachia, with its rich cornlands, was lost.

**NIVELLE'S OFFENSIVE.** In Dec., 1916, Joffre was replaced by Nivelle. By an Anglo-French agreement, Haig, with the British armies, was placed under Nivelle's command, and the British were required to extend their front, so as to give Nivelle troops for a great offensive which he intended. In Jan. and Feb., 1917, the British maintained their pressure, compelling the Germans to begin a considerable retreat to the Hindenburg line (*q.v.*), which Hindenburg hoped that his troops would be able to hold permanently and give time for the new "ruthless submarine campaign" to produce its effects. The Germans had fallen back to the Hindenburg line by early April, and the Allies had recovered 800 sq. m. of territory and the ruins of 100 villages and towns.

#### Arras-Vimy Offensive

Nivelle's plan provided for a great attack on the German position at Vimy Ridge by the British, who were to open the fighting in 1917, and were then immediately to transfer their offensive to Messines, previous to decisive operations against the Flanders coast, which was to be cleared to facilitate the campaign against the U-boats. The French, after the attack at Vimy had opened, were to assault the German positions on the Aisne, S. and S.E. of Laon. The Arras-Vimy offensive was carried out with extraordinary success. It opened on April 9, and might, by Ludendorff's admission, have brought the collapse of the German front and decisive victory, but for the weather. But the French attack on the Aisne (Apr. 16–20) failed (*see Aisne*), and the fighting at Arras had to be prolonged, though the British captured a large section of the Hindenburg "switch" line.

Nivelle was removed from command (May 15) and replaced by

Pétain, who was of opinion that the French army was in no position to continue a large-scale attack, in view of the mutinies which occurred about this time among certain units. It was decided to await the arrival of American troops (the U.S.A. having now entered the war) before attempting a great joint offensive against the Germans. The British arrangements had been dislocated and much time had been lost, so that the transfer of Haig's offensive to Flanders could not be carried out until weeks had passed. In April, 1917, the German staff was only with difficulty prevented from violating Dutch neutrality and seizing the mouth of the Schelde.

#### German Retreat in Flanders

To assist the French and cover the Russians, collapsing through the disintegration of the tsar's government and the outbreak of the revolution, the British steadily battered the German front. They stormed the Messines Ridge (June 7), regarded by the Germans as impregnable, with the small loss of 25,000 men. Before it was possible to renew the attack on the Ypres front the best weather of the year had gone, and the ground there had become as treacherous and difficult as that on the Somme. Over it raged a series of battles during the late summer and autumn, in which the Germans were slowly forced back with heavy loss, though the British casualties were also extremely heavy.

**THE SUBMARINE MENACE.** After Jutland there was no large-scale fighting at sea. The German light flotillas were active, raiding the Channel repeatedly, but in several of these raids they were severely handled by the Allies. In the winter of 1916 the German government decided, after long deliberation, to repudiate the promises it had given to the U.S.A. and prosecute ruthlessly its U-boat war—never really suspended. It based its decision on an assurance, given by the German admiralty, that Britain must collapse in six months or less. On Jan. 31, 1917, President Wilson was suddenly informed that Germany would close to neutrals the waters round Britain, France, and Italy, and would thenceforth observe no restraints. The American government at once broke off diplomatic relations, and when U-boats attacked and sank American ships, declared war (April 6).

The defeat of the U-boat campaign therefore became of over-

whelming importance, because it menaced the very existence of Britain (who in April, 1917, according to Admiral Sims, had only three weeks' supply of food), and threatened to prevent the armies of the U.S.A. from reaching Europe. Early in the campaign the British losses were grave, reaching a maximum in one month of 545,000 tons sunk (April, 1917), while Allied and neutral shipping suffered little less severely. But from July, 1917, the losses slowly diminished with the introduction of the convoy system and the use of new methods by the British navy and air service against the U-boats. Food was severely rationed in Britain; existing tonnage was used more effectively; new shipping was built.

The Strait of Dover was now closed to the U-boats by a barrage (q.v.), and a similar barrage was laid (March, 1918) across the Adriatic. Minefields were carried close in to the German bases, rendering it difficult for U-boats to pass in or out, and the Flanders bases were so constantly bombed and bombarded that U-boats were driven from them. The operations culminated in the successful sinking of blockships in the entrances to Zeebrugge (April 22-23, 1918) and Ostend (May 10). The new measures checked the U-boats and the British Admiralty was able to guarantee the safety of American troops crossing to Europe. Only 56 lives were lost through U-boat action during the movement of 1,500,000 men to France (March-Sept., 1918); and of these men 48.5 p.c. were carried in British ships.

The British naval strategy in the closing period of war was thoroughly successful. The Bight of Helgoland was heavily mined, causing a German loss of 100 vessels, and was continually patrolled by British naval forces.

#### U.S. Additions to Royal Navy

In Dec., 1917, four American dreadnoughts joined the Grand Fleet, raising its force to 51 vessels of this class against 23 German ships completed. In 1918 four more U.S. dreadnoughts were dispatched to Britain for reserve and convoy duty. So thoroughly was the inferiority of their fleet realized by the German seamen that when (Oct. 28, 1918) orders were given to it to go out and fight, the crews mutinied and thus compelled the German staff to surrender. The blockade of Germany was pressed with ever-growing severity.

The loss of British shipping during the war was 7,923,000 tons from enemy action and 1,132,000 from maritime casualties (which increased owing to the need of steaming without lights and other risks). Some part of this was made good by capture or purchase, leaving a net loss of 3,443,000 tons. The total world loss was 15,053,000 tons gross.

**THE RUSSIAN DEFEAT.** The outbreak of revolution (March 11, 1917) completed the demoralisation of Russia's armies. The fleet mutinied, and wholesale desertions on land and sea took place. A tacit truce was observed between the Russian and German forces; and all the plans prepared for Russian cooperation in the great offensives of 1917 failed just when the Austrians were making overtures for peace and the Germans were in the extremest difficulty. The whole of Galicia was swiftly recovered by the Germans, and their troops entered Podolia, a prov. of S. Russia (July 29), and proclaimed the independence of a new state, the Ukraine.

#### Treaty of Brest-Litovsk

The Germans, wanting troops for the W., did not pursue, but looked to the revolutionary extremists to do their work. They captured Riga (Sept. 3), and utilised their less efficient divisions to occupy the Ukraine, whence they hoped to draw supplies. The Russian war with Germany had virtually ceased, though a definite armistice was not signed until Dec. 15. The treaty of Brest-Litovsk with Germany and Austria was concluded on March 3, 1918.

The Russian collapse would have been fatal to the Allies had it not been delayed till a date when Britain had 5,000,000 men in service, the largest Allied army then existing. Its consequences were in part repaired by the entry of the U.S.A. into the war. But whereas Russia had large armies in contact with German territory exercising actual pressure on the Germans, the U.S.A. had no armies that counted in any part of the world. Many months were needed to train American troops and then they had to be transported to Europe. Not until Sept., 1918, did they begin to exert more than a moral influence.

#### MESOPOTAMIA AND PALESTINE

In Mesopotamia, the early British successes led to a premature movement up the Euphrates in 1915 to join hands with Russia and hold the Turks. A rash advance on Bagdad by a British-Indian force of one division was followed by a

retreat to Kut (*q.v.*). Maude was appointed to the command of the British army of Mesopotamia, and strongly reinforced from India; and at the close of 1916 he advanced and after a brilliant campaign entered Bagdad (March 11, 1917). This campaign, though a secondary one, produced considerable effect in exhausting Turkey and preparing for terrific blows which Allenby afterwards dealt her in Palestine.

#### Capture of Jerusalem

In Aug., 1916, the Turks made an attempt, their second, to invade Egypt from Palestine (then part of the Turkish empire), but were defeated at Romani, and thenceforward the British advanced slowly, constructing a railway and pipe-line for water across the desert to the Palestine frontier, capturing El Arish (Dec. 21), Rafa (Jan. 9, 1917), and reaching Gaza, where, after two days' fighting, their progress was stopped (March 26-27). A second attack on Gaza (April 19, 1917) failed. Allenby was placed in command and seized Beersheba (Oct. 31). He attacked once more at Gaza (Nov. 1-8), forcing the Turks to abandon that vital strategic point. He then worked round Jerusalem, the loss of which city (Dec. 9, 1917) was a catastrophe for the Turks. Meantime, in June, 1917, a change of importance had taken place in the Balkans. Constantine was deposed from the Greek throne, and Greece, led by Venizelos, entered the war on the side of the Allies.

**CAPORETTO AND CAMBRAI.** The Austrians on land were completely defeated by the Italians on the Isonzo (Aug., 1917). This compelled the German staff very reluctantly to strike at Italy and send 7 German divisions to the Italian front. The Italians asked for British and French reinforcements and heavy artillery; some guns were lent temporarily, but, as the Americans were not then ready to place any considerable force in line, troops could not be spared from France. The Germans broke through the Italian front near the S.E. end at Caporetto (Oct. 24); the strategic position was such that the whole force had to fall back (*see* Piave). To meet the overwhelming danger strong reinforcements were sent to Italy from the W. front (5 British and 6 French divisions). The whole of N. Venetia was lost.

The battle of Cambrai (Nov. 20), fought by Haig to hold the Germans on the W. front and support the Italians, modified the whole system of tactics and restored the element of surprise. So complete

was its initial success, attained by the advance of 400 tanks, that if fresh troops had been available to exploit the victory, the German line might have been broken finally. The opportunity could not be used; the Germans concentrated and counter-attacked (Nov. 30), recovering much lost ground.

**GERMAN OFFENSIVE OF 1918.** Owing to the collapse of Russia, the Germans were able to move all their good troops to France, where 34 divisions arrived from the E., replacing tired units and raising the total German strength in the W. to 197 divisions against an Allied strength of 169 divisions. For the first time since Sept., 1914, the Allies had no superiority in numbers. The weakest part of the Allied front was the British line between Cambrai and the Oise held by Gough's 5th army. Its S. section had been previously in the hands of the French, and had been captured during the German retreat of 1917. It had not been provided with good rear-defences, as it had been taken over only in Jan., 1918, and the supply of labour was inadequate. It was at this point that the Germans decided to make their first thrust.

The German command was now aware that the U-boat campaign had failed; and if the war was to be won, the only possible resource was to destroy the British and French armies, by severing them and rolling up the British army first. It believed that the French troops were tired and that the morale of the British had been shaken by propaganda behind the line. The actual attack opened on March 21, 1918, by which time Foch had been appointed supreme commander of the Allies in the W.

#### "Backs to the Wall"

On April 9 the Germans attacked at Armentières, driving a deep wedge, which they steadily widened, into the British front. They captured the Messines Ridge, thus imperilling the British position at Ypres and the defence system of the Channel ports. They took Kemmel Hill (April 25) from the French. The position could scarcely have been more critical. It was on April 11 that Haig (*q.v.*) issued his "backs to the wall" order, and the troops responded with surpassing spirit. Again the German attack died down.

During this offensive the Germans made slight gains near Amiens which brought them within 7 miles of that vital point and enabled them to keep the main

railway to Paris under constant fire. But the Australians beat off all further attacks and even won some ground.

The Germans renewed their attack on May 27, when with 25 divisions they attacked 4 weak British and 4 tired French divisions on the Aisne, between Soissons and Reims, and reached the Marne once more on a front of 10 m. E. from Château-Thierry. Extending this advance, they gained a point only 45 m. from Paris, which city they had bombarded from March 23 onwards with special long-range guns installed near Laon and firing at a distance of 70 m. At the same time they carried out large-scale air raids on Paris.

#### Turn of the Tide

Early in June, Foch had to effect withdrawals between Montdidier and Château-Thierry before German pressure, but though the Germans appeared on the eve of success, on June 13-14 they were stopped. This was in reality the passing of the crisis, and the Allies had now a slight numerical advantage. On July 2 the American government announced that a million Americans had already sailed for Europe, so that Germany had not a moment to lose.

The German front at this moment formed a vast semi-circle, bulging into the Allied front, so that the German staff could strike at any point and hold their reserves in a central position which would not betray their intentions. Foch, however, obtained accurate information as to the place and date of the intended offensive, and took admirable measures to meet it. Delayed by stormy weather, it was not until July 15 that the Germans advanced.

For the second time in the war the Marne proved itself a river of fate; the Germans crossed it, but were heavily repulsed at Reims, and S. of the Marne they were quickly brought to a standstill N.W. of Épernay. This was the high-water mark of their advance. By July 16 the German staff knew that the attack had failed.

**FINAL BATTLES.** Foch's preparations for a return stroke were complete. Early on July 18, French and American divisions delivered a sudden attack on the exposed German flank between the Aisne and Château-Thierry. They forced a German retreat across the Marne. Foch pressed the Germans continually, and drove them steadily, if slowly, back, while French, British, American, and Italian

troops attacked on both sides of the Marne salient, and endeavoured to hold the enemy and pinch him off.

The German reverse on the Marne had great effect in shaking Austrian and Bulgarian confidence, and on Aug. 3 the German staff admitted "our strategical plan of attack had failed."

On Aug. 8, Haig and the British, with the 1st French army co-operating, attacked before Amiens, employing 400 tanks. The Germans were completely surprised, and 6 or 7 German divisions of high quality were destroyed, and the severest defeat of the whole war up to that date was inflicted on the German army. Montdidier was retaken by the 3rd French army, which attacked when the Germans elsewhere gave way.

The British "Hundred-Days' Battle" had begun. From Aug. 8 Haig maintained his persistent assault on the German front with only the briefest intervals for the repair of the railways and roads. Such attack was made possible because of the unity of command and the abundant supply of munitions now at his disposal.

#### Germany's Desperate Efforts

Ludendorff pressed both Austria and Bulgaria to send reinforcements to the W. front. Bulgaria refused, and Austria could be induced only to send artillery and to promise a few divisions, which were speedily engulfed in the general disaster. All the difficulties of the German staff were accentuated by a brilliant attack delivered by the French between Noyon and Soissons (Aug. 20). The British pressed their advantage, attacking with equal violence on the old Somme front, and retaking Albert. On Aug. 21-26 they attacked and captured the important positions abutting on the N. end of the advanced Hindenburg (or Wotan) line, near Arras.

The Wotan line itself was stormed by Canadian and British troops (Sept. 2). The Germans were flung back on the main Hindenburg line of fortifications before Cambrai, which were of extraordinary strength, and had the advantage of water-protection in their front as a security against tanks. The German armies were showing signs of exhaustion, and Ludendorff bitterly complained that he was not properly supported by the civilians in the government.

At this juncture the Americans under Pershing began their first large scale operation (Sept. 12), and captured the deep salient in

the Allied front at St. Mihiel, and cleared the great Paris-Avrucourt double-track railway which Foch wanted for the development of his manoeuvres. Simultaneously the British closed upon Cambrai and made ready to assault the enormous Hindenburg works, and to force the defences of that pivotal point and junction.

This was the gravest operation of the whole Allied offensive, and there were many doubts as to whether it could succeed, such were the natural and man-made obstacles. The prelude was the opening of a great American offensive on both sides of Verdun, through the Argonne region of forest, hills, and swamps, a terrain of the greatest difficulty, rendered more difficult than ever by heavy rains. The French supported this offensive by an attack W. of the Argonne, so that the Germans were held firmly.

Covered by an unexampled concentration of 4,200 guns, the British began the storming of the Hindenburg line. The Canal du Nord was crossed (Sept. 27), and the British pushed clean through the Hindenburg line near its N. end. On Sept. 28 the battle-front was prolonged by an Allied advance in Flanders which captured the Messines ridge, cleared Ypres, and resulted also in a great gain of ground. On Sept. 29 the British crossed the St. Quentin canal (S. of Le Catelet), and broke the Hindenburg system S. of Cambrai; the same day the Canadians fought their way into the suburbs of Cambrai.

#### Bulgaria Sues for Armistice

Meanwhile, on Sept. 15 the Allies on the Salonica front attacked the Bulgarians N. of Monastir. The Serbians broke right through the Bulgarian front, while the British and Greeks pinned down the forces before them, in the immediate N. of Salonica. Owing to the dash and determination of the Serbians the victory became a decisive one (Sept. 21).

On Sept. 26 the Bulgarian government asked for an armistice, which was signed on Sept. 29. The news of this surrender caused financial panic in Germany, as with it railway communication between Germany and Turkey was cut and the fall of Turkey at an early date assured. Rumania had been compelled by the defection of Russia to sign an armistice with Germany (Dec., 1917), followed by a definite peace. Throughout early 1918 the Austrian emperor Charles had been anxious for peace owing to grow-

ing internal difficulties and want of food. In June, to obtain supplies which the Germans would grant on no other conditions, he was forced to undertake an offensive in Italy. The support of 100,000 German troops had originally been promised him by Ludendorff, but owing to the failure of the earlier German offensives in France to secure decisive results, they could not be sent.

#### Austria and Turkey Collapse

On Sept. 15 the Austrian emperor issued a peace note, which the Allies rejected, and orders were issued for a great Italian offensive. The battle of Vittorio Veneto (*q.v.*) ended the Austrian resistance, and on the night of Nov. 3 the Austrians signed an armistice. The surrender of Turkey preceded that of Austria by a few days.

On Oct. 1 Ludendorff urged the German government to open negotiations for an armistice in the W. as quickly as possible. The civilians of the German government thought he had lost his nerve completely, but many other officers at the German headquarters shared his view. Prince Max of Baden was appointed chancellor and attempted to open negotiations with President Wilson, on the basis of his Fourteen Points (*q.v.*) set forth in Jan., 1918.

The British continued their advance. On Oct. 8 they opened the battle of Le Cateau, and captured Cambrai on the following day. The whole German line tottered; Laon, a vital junction, fell to the French (Oct. 13); Roulers, in Flanders, was taken on Oct. 14, and Menin on the following day. In danger of envelopment, the Germans abandoned the Flanders coast, and the Allies occupied Ostend (Oct. 17) and Zeebrugge (Oct. 19). The Germans had to evacuate Lille and Douai on Oct. 17, and the Allies recovered Tourcoing and Roubaix next day. On Oct 17 the British broke through the German front on the Selle. On Nov. 1 they opened the battle of the Sambre, which brought the recovery of Valenciennes and an advance over the old battlefield of Mons. That place was captured, and passed by the British just as the armistice came into force (Nov. 11).

Meantime, the French had pushed forward on the section of front between the main British attack and the American Argonne advance. The Americans pressed N., threatening more and more the German line of retreat. They took Stenay (Nov. 4), and continued their

progress till they reached the suburbs of Sedan.

Germany now knew she was beaten—not only in the military field but by the severe pressure of the Allied blockade, which crippled her production. In the long struggle of attrition by exhaustion of man-power, she was faced with the prospect of meeting the new and vigorous reserves of man-power from the U.S.A., as yet scarcely tapped. The inescapable facts were pressed home by intensive British propaganda.

To obtain peace, the German government on Oct. 20 ordered its U-boats to cease attacking passenger ships; it was warned by President Wilson (Oct. 23) that the only possible armistice would be one rendering a renewal of the war out of the question, and that the Allies could never trust William II. The American president had previously referred the Germans to the Allied military advisers for the conditions. Ludendorff resigned on Oct. 27. On Nov. 7, revolutionaries seized Kiel and Hamburg, and German delegates left for Foch's headquarters to negotiate the terms of the armistice. When informed of the conditions settled for them, they protested vehemently, but their Government on Nov. 10 announced by wireless its acceptance. William II had abdicated under pressure on Nov. 9; he fled to Holland, accompanied by the crown prince.

#### Conditions of the Armistice

The main condition of the armistice (signed 5 a.m., Nov. 11) were: Cessation of operations six hours from signature. Evacuation within 15 days of Belgium, France, Alsace-Lorraine, and Luxemburg by all German forces. Repatriation of all prisoners and civilians taken by the Germans. Surrender by them of 2,500 heavy and 2,500 field guns, 25,000 machine-guns, 3,000 mine-throwers, and 1,700 aeroplanes, including all night-bombing machines. Evacuation by the Germans and occupation by the Allies of all German territory W. of the Rhine, with, in addition, bridgeheads of 20 m. radius on the E. bank of the Rhine at Cologne, Coblenz, and Mainz, to which other bridgeheads at Kehl (opposite Strasbourg) and Mannheim were afterwards added. Surrender of 5,000 engines, 150,000 wagons, and 5,000 motor-lorries.

Reparation for damage done to be paid, "all future claims and demands of the Allies remaining unaffected." All submarines to be

surrendered. Six battle cruisers, 10 battleships, 8 light cruisers, and 50 destroyers to be interned under Allied surveillance, and all other German warships to be disarmed. The blockade to continue till definite peace; German minefields to be removed; all naval aircraft to be immobilised. All territory outside Germany to be evacuated. The duration of the armistice, for 36 days in the first place, was repeatedly extended—until the treaty of Versailles was signed (June 28, 1919). On Nov. 21, 1918, the German surface ships arrived at Rosyth for internment; their crews scuttled most of them at Scapa on June 21, 1919.

The confusion in the German rear was great; transport and supply were breaking down; roads were choked; troops were deserting; losses in men and material had been irreparable. All the German monarchies had fallen. Foch's forces when the armistice was signed held a line E. of Ghent, Mons, Maubeuge, and Hirson, thence turning S.E. through Mézières, Sedan, Stenay, and Ornes to S. of Metz.

**THE AIR WAR.** The bombing attacks by Zeppelins and aeroplanes upon the civilian populations of British and French cities throughout the war are described in the article Air Raids, as are the later raids made on industrial centres in Germany by Allied aircraft. In Great Britain the Zeppelin arm was met and broken in the autumn of 1916, but the menace from the aeroplane developed steadily. As the British government refused, until late in 1917, to carry out reprisals, the Germans derived great advantage from this air war. They neutralised and held fast in England some 100,000 men with large numbers of machines, absorbed in defence. The importance of air warfare grew daily and was felt at Arras and Messines, where the British airmen carried all before them; but the Germans maintained a determined competition to the end. (See Royal Air Force; Royal Flying Corps.)

**THE GERMAN COLONIES.** The German colonies were attacked early in the war, and one after another were captured, though not without severe fighting in some cases. The German fortress of Tsingtau (Kiao-chau), on the E. coast of China, was captured by a Japanese expedition, aided by a small British contingent, on Nov. 7, 1914. Japan had declared war on Germany (Aug. 23, 1914)

and cooperated in the convoy of British forces to Europe and in the cruiser operations in the Pacific and Indian Oceans against von Spee and the Emden, but she took little further part in the war, beyond sending a number of destroyers to the Mediterranean, where they did excellent work against the U-boats. She occupied the Caroline and Marshall Islands in the Pacific. Samoa was seized by New Zealand troops, and German New Guinea and adjacent islands by Australian troops, aided by the Australian navy.

#### Germany's African Possessions

Of the vast German territories in Africa, Togoland was conquered by the British and French in 1914 and was divided between them. Cameroons was occupied by British and French forces in 1916. German South-West Africa, one of the most valuable of the German colonies, equipped for a base against the Union, was reduced by Botha and Smuts in a remarkable campaign which closed July 9, 1915. South-West Africa was thenceforward administered by the Union of South Africa.

In German East Africa, owing to the great extent of territory, the destruction of the German forces was difficult. British, Belgian, and Portuguese forces cooperated, and by the close of 1916 the coast and central railway to Tanganyika were in Allied hands. But the war smouldered on, though the German forces were small, and at the armistice there were still about 1,500 German and native troops in arms.

**THE BRITISH CAMPAIGNS.** The burdens supported by the British and the services they rendered to the Allies will best be understood from the official list of 26 campaigns in which British troops took part, issued by the Army Council. They were: France and Flanders, 1914-18; Italy, 1917-18; Macedonia, 1915-18; Dardanelles, 1915; Sudan, 1916; W. Egypt, 1915-16; E. Egypt and Palestine, 1914-18; Hejaz, 1916-18; S. Arabia, 1914-18; Mesopotamia, 1914-18; S. Persia, 1915-19; E. Persia, 1915-19; N.W. Persia and Caspian, 1918; N.W. India, 1914-18; Murmansk, 1918-19; Archangel, 1918-19; Siberia, 1918-19; China, 1914; Australasia, 1914; E. Africa, 1914-18; S.W. Africa, 1914-15; Togo, 1914; French W. Africa, 1917; Cameroons, 1914-16.

**RESETTLEMENT OF EUROPE.** The treaties which formally ended the war were those of Versailles,

concluding peace with Germany, June 28, 1919, ratified Jan. 10, 1920; St. Germain-en-Laye, with Austria, Sept. 10, 1919, ratified July, 1920; the Trianon, with Hungary, June 20, 1920, ratified a year later; Neuilly, with Bulgaria, Nov. 27, 1919; and Sévres, with Turkey—though this last was never operative, being signed at Constantinople in Aug., 1920, by a Turkish government with no real authority; it was superseded by the treaty of Lausanne, July 24, 1923. These treaties are dealt with in greater detail under their own headings.

#### Europe after the War

The Versailles treaty established the League of Nations (*q.v.*), which for the next 20 years was to exert a varying weight of influence on the direction of international affairs. The German empire of the Hohenzollerns collapsed, as did the Austro-Hungarian empire of the Hapsburgs. Germany became a republic. She lost all her overseas colonies, mostly to Great Britain and France, returned Alsace and Lorraine to France, and underwent several modifications of her boundaries in favour of Belgium, Lithuania, and reborn Poland. Austria and Hungary became two states, each republican in form. The area of Austria was greatly diminished by the cession of territory to Italy and to the new states of Czechoslovakia and Yugoslavia, created in pursuance of Wilson's policy of the right of self-determination. The old kingdom of Poland re-emerged as an independent republic, with a "corridor" to the Baltic. The defeated Russian empire was rent by violent revolution and had ceased for the time being to hold any place in world councils. Her break-up permitted the establishment of the four Baltic independent republics of Finland, Latvia, Lithuania, and Estonia.

Great Britain emerged from the struggle stronger in prestige and power. At the close of the war she had by far the strongest, best trained, and best equipped army in the field. The status of the British dominions was enhanced by their great contribution to the result, each receiving separate representation in the League of Nations, but the links binding them to the British crown were seen to be more firmly re-forged in the common endeavour. Palestine and Iraq were placed under British mandate by the League.

As already indicated, the financial loss entailed by the combat-

ants was unprecedented. Currency values throughout the world were deeply affected, depreciating in some countries with tragic swiftness. But more serious, because irremediable, was the loss to the world of 8,000,000 of its young manhood. In addition, large centres of population in central Europe were on the verge of starvation. Less easy to assess was the depreciation in moral and philosophical values, as seen in a wider substitution of cynicism and opportunism for the older ideals which had been based on a firm belief in human progress. Not only had the German aggression and wanton breaking of faith revealed the frailty of such influences as make for a higher form of civilization; but the length of the war, and its unprecedented horrors and squalors, had brought about a vast sense of disillusionment and an exhaustion of mental and moral effort, tending too often to a mood encouraging inertia. These tendencies were to cloud and hamper the world's activities for many years.

**Bibliography.** War Books: a Critical Guide, C. Falls, 1930, is a useful guide to the vast literature of the First Great War, but is incomplete in that it does not include books on the causes of the war or on the peace-making; moreover, many books, including at least one of the first importance, have been published since 1930. It has been stated that the British Museum library catalogue contains as many items on the First Great War as on the Holy Bible.

The British Official Histories, issued by the Imperial Defence Committee, fill many volumes, some of which had not been published even by 1947. They cover military operations in Egypt and Palestine (2 vols.), France and Belgium (14 vols.), Gallipoli (2 vols.), E. Africa, Mesopotamia (4 vols.), Togoland, and Italy; histories of all the divisions of the British army in the war (6 vols.), naval operations (5 vols.), the merchant navy (3 vols.), seaborne trade (3 vols.), air warfare (6 vols.); and medical services, etc. (12 vols.).

Other general historical surveys include Short History of the Great War, A. F. Pollard, 1920; Outline History of the War, G. V. Carey and H. S. Scott, 1928; Popular History of the Great War, 6 vols., ed. J. A. Hammerton, 1934. A history published during the war, and therefore subject to stringent censorship, yet valuable for its contemporary standpoint, is The Great War, ed. H. W. Wilson and J. A. Hammerton.

British Documents on the Origins of the War, ed. G. P. Gooch and H. W. V. Temperley, 11 vols., 1928-38, is an outstanding and

authoritative publication. Temperley's History of the Peace Conference, 1920-21, is a standard work.

More personal narratives, though each indispensable to full appreciation of the subject, are The World Crisis, W. S. Churchill, 6 vols., 1923-30, and War Memoirs, D. Lloyd George, 6 vols., 1933-36; also The Truth about the Peace Treaties, D. Lloyd George, 1938. Leading figures who contributed their memoirs were Lord French (1919), Lord Jellicoe (1919), Falkenhayn (trs. 1919), Ludendorff (trs. 1919), Tirpitz (trs. 1919), Hindenburg (trs. 1920), Kluck (trs. 1920), Scheer (trs. 1920), Townshend (1920), Robertson (1921), the ex-Kaiser (trs. 1923), Masaryk (trs. 1927), Benes (trs. 1928), Prince Max of Baden (trs. 1928), Poincaré (trs. 1928).

Among innumerable other books of record and reminiscence may be mentioned The First World War, C. & C. Repington, 2 vols., 1920; Tanks in the Great War, J. F. C. Fuller, 1920; A Naval History of the War, Sir H. Newbolt, 1920; With the Russian Army, Sir A. Knox, 1921; Personalities and Reminiscences, R. L. Bullard, 1925; The Intimate Papers of Col. House, ed. S. Seymour, 4 vols., 1926-28; Gallipoli, J. Masefield, 1926 edn.; Revolt in the Desert, T. E. Lawrence, 1927; My Mystery Ships, G. Campbell, 1928; Haig, Duff Cooper, 2 vols., 1935-36.

More philosophical or psychological in their study of individual human reaction to the war are such "literary" books as A Private in the Guards, S. Graham, 1919; Realities of War, Sir P. Gibbs, 1920; Disenchantment, C. E. Montague, 1922; Undertones of War, E. Blunden, 1928; The Weary Road, C. Douie, 1929; War Letters to a Wife, R. Feilding, 1929; Memoirs of an Infantry Officer, S. Sassoon, 1929.

The following novels dealing with the war may be cited as "documents" of some value: Mr. Britling Sees It Through, H. G. Wells, 1916; Under Fire, H. Barbusse, trs. 1918; The Secret Battle, A. P. Herbert, 1919; The Four Horsemen of the Apocalypse, V. Blasco Ibañez, trs. 1918; The Barber of Putney, J. B. Morton, 1919; Command, W. M'Fee, 1922; Some Do Not (1924), No More Parades (1925), A Man Could Stand Up (1926), and Last Post (1928), all by F. Madox Ford; The Spanish Farm Trilogy, R. H. Mottram, 1924-26; These Men Thy Friends, E. Thompson, 1927; The Case of Sergeant Grischa, A. Zweig, trs. 1925; War, L. Renn, trs. 1929; All Quiet on the Western Front, E. M. Remarque, 1929; Class 1902, E. Glaeser, trs. 1929; Her Privates We, "Pte. 1902," 1930; All Our Yesterdays, H. M. Tomlinson, 1930; The Patriot's Progress, H. Williamson, 1930. The "soul of the war" is also revealed in the works of various soldier-poets, e.g. Blunden, Grenfell, Hodgson, Nichols, Owen, and Sassoon, as it

is in the paintings of such artists as Orpen, Nevinson, John and Paul Nash, Kennington, H. S. Williamson, and many others whose work is exhibited in the Imperial War Museum, London.

A remarkable phenomenon was the sudden vogue in Great Britain for books about the war, especially fiction, in 1929-30, until the public was surfeited and the demand and supply ceased as suddenly as they began. It was the more strange in view of the unpopularity of the same subject during the preceding ten years, although a few outstanding war novels had appeared, only to be neglected. The change in taste was due in part to the success on the London stage of R. C. Sherriff's war play *Journey's End*, and in part to the extensive advertisement given in 1929 to E. M. Remarque's *All Quiet on the Western Front*, which sold extravagantly. Very little of the flood of war books which followed merited permanence.

**First Offender.** A legal term. In England at common law there was always jurisdiction to bind over any offender to be of good behaviour. But since many magistrates seemed to ignore this, the First Offenders Act, 1887, was passed, giving all courts of criminal jurisdiction power to bind over first offenders instead of punishing them. The Probation of Offenders Act, 1907, extended this power to all cases, whether first offences or not; and gave the court power to order any first offender to be placed under the supervision of some person named (generally the probation officer) for a period. The order may also provide that the offender shall abstain from intoxicating liquor, and may prescribe conditions as to his residence. See *Borstal System*; *Children*.

**First of June, BATTLE OF.** Fought in 1794, the first great naval action in the War of the French Revolution. France, though victorious on land, was in a situation little short of desperate. It was the epoch of the Terror, the harvest of the previous year had been poor, and famine was threatened. The British blockade was crippling supply. The Committee of Public Safety had endeavoured to relieve the situation by purchasing grain in the U.S.A., and a convoy of 116 vessels was dispatched, which approached the French coast towards the end of May. Rear-Admiral Nielly was sent out to meet the convoy, which Lord Howe was instructed to intercept.

The main French fleet, under Admiral Villaret-Joyeuse, left Brest on May 16 to cover the

arrival of the great grain convoy, and it was not until the 28th that Howe sighted his adversary. A good deal of fighting preceded the great action of June 1, in which Howe's fleet was shown to be the superior fighting force. His plan was to attack the enemy in line, van to van, centre to centre, and rear to rear, to break through the opposing line, and fight to a finish on the lee side. His ships were to pass through the intervals in the French line, but approach was slow, and the order could not be completely executed.

The *Bellerophon*, Russell, Royal Sovereign, and other ships attacked to windward, and several French ships thus slipped or were driven away. The Marlborough and Queen Charlotte (Howe's flagship), broke through the line, and delivered their broadsides with shattering fire. Captain Harvey, in the Brunswick, endeavoured to drive through the French line, but brave Captain Renaudin, in the *Vengeur*, stopped his way and the two ships were locked together in a furious struggle which has become famous, until the *Vengeur*, swept and broken by fire, went down with all her company. At every point the action was fought with the utmost gallantry and resolution on both sides. Six prizes remained in English hands, and the success, if not decisive, was enough. For two years to follow there was no great action at sea. The French, too, claimed a victory, for their fleet had not been destroyed, and their convoy reached Brest in safety.

**First Republic.** Name given in France to the period from 1792 to 1804. On Sept. 21, 1792, the convention declared the monarchy at an end and the country a republic. This lasted until May, 1804, when Bonaparte was declared emperor. See *French Revolution*; *Napoleon*.

**Firth.** Name given to a narrow inlet or arm of the sea found on the coasts of Scotland. Most of them are estuaries or gulfs into which rivers discharge themselves, e.g. firths of Clyde, Tay, and Forth, but Pentland Firth is a broad strait or channel. Firths are, as a rule, valleys which have been flooded by the sea.

**Firth, SIR CHARLES HARDING** (1857-1936). A British historian. Born in Sheffield, March 16, 1857, he was educated at Clifton and Balliol College, Oxford. He became fellow of All Souls, 1901, and was chosen in 1904 to succeed York Powell as regius professor of modern history at Oxford. He

edited Ludlow's *Memoirs*, 1894, *The Clarke Papers*, and *The Memoirs of Colonel Hutchinson*; wrote monographs on Cromwell, 1900; Cromwell's Army, 1902; and continued S. R. Gardiner's unfinished history of the Commonwealth and Protectorate. Firth's work threw much light on the middle decades of the 17th century. He was knighted 1922, retired 1925, and died Feb. 19, 1936.

**Firth, MARK** (1819-80). British manufacturer. Born at Sheffield, April 25, 1819, he was the son of an artisan in the steel industry. In 1843 his father, brother, and himself together opened a steel furnace. Mark was the moving spirit of this enterprise, and soon made it one of the largest concerns in Sheffield. The Norfolk Works were built to cope with the increasing business, while others were erected outside the city. Firth died Nov. 28, 1880. Known as a philanthropist, he built almshouses at Rammoor, and founded Firth College, the nucleus of the university of Sheffield.

**Fisc** (Lat. *fiscus*, treasure chest). Term used in England in the Middle Ages for what is now the treasury, the account into which the public revenues are paid. From it comes the more familiar word *fiscal*. See *Fiscus*.

**Fischart, JOHANN** (c. 1545-90). German satirist. He was born in Alsace, and studied at Worms. He travelled in Holland, England, France, and Italy, and studied law in Strasbourg; he had already published lampoons and satires against the Jesuits and others, and a free rendering of Gargantua into German, 1575, when he was appointed magistrate at Forbach, near Saarbrücken, 1583. Under various pen names, Fischart did good service to the Lutheran movement. The best known of his reprinted works is the simple verse narrative *Das Glückshaff Schiff von Zurich* (The Lucky Boat of Zürich), 1576.

**Fischer.** Name of several German scientists. Emil (1852-1919), born Oct. 9, 1852, was awarded the Nobel prize for chemistry in 1902. His main work was in the preparation of synthetic sugars and research into problems of fermentation; he discovered the soporific veronal; his attention to nitrogen compounds was given at a time when German sources of munitions were failing. He died July 15, 1919. Eugen, born June 5, 1874, became director of the Kaiser Wilhelm Institute for anthropology and eugenics. Franz, born March 19, 1877, was part-inventor of the

1 *Peristedion cataphractum*, European seas 2 *Dactylopterus volitans*, Mediterranean and tropical Atlantic 3 *Holocanthus villaris*, Atlantic coasts of tropical America 4 *Gomphosus coeruleus*, Indian Ocean 5 *Cheilodactylus*, Indian Ocean and West Pacific 6 *Acanthurus veliei*, Polynesia 7 *Hemirhamphus macrolepidotus*, Indian Ocean and Malay Archipelago 8 *Balistes aculeatus*, tropical seas 9 *Holocanthus annularis*, Malay Archipelago 10 *Holocanthus asini*, Red Sea 11 *Pterois miles*, Red Sea and Indian Ocean 12 *Amphiprion chrysozoster*, Indian Ocean 13 *Balistes conspicillum*, Indian and Pacific Oceans 14 *Fulcris fulgurata* and 15 *Coris aygula*, Red Sea Indian and West Pacific Oceans 16 *Cyprinus auratus*, China Sea 17 *Lipibulus insidiator*, Indian Ocean and Malay Archipelago

**FISHERIES: ACTIVITIES IN THE WORK OF THE NORTH SEA FISHING FLEET**

Fischer-Tropsch process (*q.v.*) for gasifying coal. Hans, born July 27, 1881, became professor of chemistry at Innsbruck, Vienna, and Munich, and on being the first to prepare haemoglobin synthetically was awarded the Nobel prize for chemistry in 1930.

**Fischer, JOHANN GEORG VON** (1816-97). A German poet and dramatist. He was born Oct. 25, 1816, at Gross-Sussen, Wurttemberg. Having studied botany and literature at Tübingen, he was in 1846 appointed professor at the Stuttgart Oberrealschule. In 1854 he published his first volume of poems, and in 1896 his last, *Mit Achtzig Jahren* (In my Eightieth Year). He also published some dramas, notably *Saul*, 1862; and *Kaiser Maximilian von Mexiko*, 1868. His lyric poetry is characterised by natural beauty and exalted tone. He died at Stuttgart, May 4, 1897.

**Fischer, KUNO** (1824-1907). German philosophical writer. Born at Sandewalde, Silesia, July 23, 1824, after studying at Leipzig and Halle he became a tutor at Heidelberg, but owing to his advanced ideas was compelled to discontinue his lectures. For 16 years he was professor at Jena, and in 1872 succeeded Zeller as professor of philosophy at Heidelberg, where he died, July 4, 1907. A modified Hegelian in his views, he did much to popularise Kant. His greatest work, *History of Modern Philosophy* (latest ed. 1897-1904), is distinguished by lucidity and brilliancy of style and by wide knowledge.

**Fischer-Tropsch Process.** A method for synthesising hydrocarbon oils and waxes from the gases hydrogen and carbon monoxide, prepared from coal, coke, lignite, methane (natural gas), etc. Invented in Germany by Franz Fischer and Hans Tropsch in 1925, it was intensively developed in that country to produce synthetic liquid fuels. During 1939-45 nine Fischer-Tropsch plants with a total annual output of about 500,000 tons of synthetic oil were in operation in Germany.

In the process, coal, etc., is converted into a gas mixture containing one part of carbon monoxide to two parts hydrogen by treatment at high temperatures (180°-200° C.) with air (or oxygen) and steam. The gas mixture is purified from sulphur compounds and passed at a pressure of one to ten atmospheres through specially-designed reaction vessels containing a catalyst (*q.v.*) of which

cobalt is the most important constituent. After two or three stages of catalytic treatment, 80 p.c. of the reacting gases is converted to the desired products, which are recovered from the gas stream by cooling and absorption processes. The products, almost exclusively straight-chain paraffin and olefine hydrocarbons, are separated by distillation into the following fractions: Compressed liquefied gas, 10-15 p.c. by weight; motor spirit, 30-50 p.c.; diesel oil, 25-35 p.c.; wax, 10-25 p.c.

The compressed gas (propane, butane, propylene, and butylene) is used as portable fuel or as raw material for the manufacture of chemicals. The motor spirit (octane number, motor, 50) must be blended with higher grade fuel or extensively reformed to make it suitable for modern petrol engines. The Diesel oil (cetane number 78) is of exceptionally high quality and best used in admixture with low grade oils. The wax can be used in polishes, for electrical insulation, paper impregnation, etc. By further chemical treatment of the above primary products, high grade lubricating oils, soap, edible fat, and detergents can be prepared. See Hydrogenation; Low Temperature Carbonisation.

**Fiscus.** Latin word, meaning a purse, which came to be applied to the treasury of the emperor in ancient Rome, as opposed to the *aerarium* (*q.v.*), the treasury con-

trolled by the senate. As the power of the latter declined, the *fiscus* gradually became the state treasury for the whole empire, the functions of the *aerarium* being ultimately limited to the municipal finances of Rome.

**Fiset, SIR EUGENE MARIE JOSEPH** (b. 1874). Canadian surgeon and soldier. Born at Rimouski, March 15, 1874, and educated at Rimouski and Laval university, he completed his medical training in London and Paris. Fiset served with the Canadian contingent in S. Africa; in 1903 he reached the rank of colonel. Until 1906 he was director-general of medical services, and was then deputy-minister of militia and defence until 1923. He had much to do with equipping the Canadian forces for the First Great War. In 1917 he was knighted. He was M.P. for Rimouski from 1924 and lieutenant-governor of Quebec from 1939.

**Fish.** One of the classes or kingdoms of the animal world. Fishes may be defined as cold-blooded vertebrate animals, living in water, and breathing by means of gills. In a few a primitive lung is present, and the fish can breathe air directly. The limbs, when present, are paired fins; there are also unpaired fins which consist of folds or outgrowths of the skin. The body generally tapers towards the extremities, and is specially adapted for rapid passage through the water with the minimum of

Fish. Diagrams illustrating the structure of fishes. Upper, skeleton of common perch; a, pre-maxillary bone; b, maxillary bone; c, under jaw; d, palatine arch; e, cranium; f, inter-operculum; g, g', vertebral column; h, pectoral fin; i, ventral fin; k, l, dorsal fins; m, anal fin; n, n', caudal fin. Lower, internal anatomy of carp; br, branchiae or gills; c, heart; e, intestinal canal; o, ovaries; a, a', anus; o', oviduct

resistance. Sometimes the body is greatly flattened—either vertically, as in the rays, or laterally, as in the sole and turbot. In nearly all the genera the heart has two chambers and contains venous blood only. With few exceptions fishes reproduce their kind by eggs which are deposited in the water and fertilised by the male after they leave the body of the female, though a few species bring forth living young.

Fishes are found in all waters, both marine and fresh, and at almost all temperatures. Something like 2,300 species of fresh-water fishes are known to science; about 3,500 species are littoral; many others inhabit the seas far from land; and about 100 genera, including numerous species, have been met with in the lowest depths of the ocean.

#### Functions of the Fins

The skeletons of fishes are usually bony; but in the Elasmobranchs they are cartilaginous in character. In addition to the skeleton supporting the body outline and the limbs, there are often numerous bony rays supporting the unpaired fins also. The tail, with the caudal fin, is the principal propelling instrument, the paired fins being used as auxiliaries and for steering. The unpaired fins on the dorsal and ventral sides of the body serve mainly as balancers. The scales with which the body is more or less covered are sometimes bony. They are often nearly allied to teeth in structure and contain dentine.

Fishes breathe by extracting the oxygen contained in water, which is usually taken in by the mouth and passed out through the gill-clefts on either side at the hinder part of the head. In its course it passes over a series of arches or plates, abundantly supplied with blood-vessels, and the oxygen is thus brought into contact with the blood much as in the lungs of terrestrial animals. Most fishes are well supplied with teeth, which in some families are numerous. They may be confined to the edges of the jaws, but are often found on the palate and even on the gill arches and in the throat. There may be both cutting teeth and grinding ones, the latter often taking the form of plates. They usually grow to join the surfaces of the bones of the mouth, but are sometimes found in sockets. They are usually replaced, when worn down, by fresh teeth.

Fishes have in most species well-developed eyes, and their power of

vision is good. A few genera, found in underground streams or in the greatest depths of the ocean, are without functional eyes. Experiment proves that most species can hear well; and their sense of touch is highly developed, the barbels which are found around the mouth in many species being used for this purpose. Whether the sense of taste is as well developed is less certain. In colour fishes vary greatly, from the most sombre tones to the most brilliant hues. As a rule, the upper surface is darker than the lower, an arrangement which helps to make them inconspicuous. Protective coloration is often present, notably in the flat fish, which often so exactly resemble the mud and sand that they are very difficult to see when lying on the bottom. Many species, especially in the tropics, are gorgeously coloured and variegated to match the seaweeds and corals of their environment.

In the matter of diet fishes vary greatly, and almost everything, both animal and vegetable, that lives in the water is preyed upon by one species or another. Small crustaceans and molluscs form the most important item in the food of most fishes; but many prey on smaller fishes, and others browse on the aquatic vegetation. Some swallow mud and extract nutriment from it. As a rule, the appetite of fishes is large, and some species have such expansive powers that they will even swallow other fishes larger than themselves. Nearly all fishes are edible, though many are coarse and indigestible and a few appear to be actually poisonous. But the poor reputation of certain species is simply due to unskilful and unsuitable cooking. Fresh-water fishes, with the exception of salmon and trout, are as a rule muddy or insipid flavour compared with the marine fishes.

#### Divisions of Fish Kingdom

The class Pisces—the fishes—is usually divided into two great grades: cartilaginous fishes and bony fishes. In the former group are included the sharks and rays together with a number of extinct species and the curious Chimaera. In the bony fishes are included the lung fishes, the Crossopterygians which were believed all to be extinct until one was caught alive off South Africa in 1938 and named *Latimeria*, and all the familiar living forms. The Holosteii, the group to which the familiar forms mostly belong, though now extremely widely distributed in the

oceans of the world, where they are enormously plentiful, are probably derived from fresh-water forms which have secondarily invaded the sea, displacing the many salt-water forms which flourished in past ages.

**Bibliography.** The Migrations of Fish, A. Meek, 1916; The Biology of Fishes, H. M. Kyle, 1926; A History of Fishes, J. R. Norman, 1931; The Fishes of the British Isles, J. T. Jenkins, 1942; The Fish Gate, M. Graham, 1943.

**Fish, HAMILTON (1808-93).** An American statesman. Born Aug. 3, 1808, in New York, he became a barrister in 1830. In 1842, as a Whig, he was returned to congress, and in 1848 he became governor of New York state. In 1851 he was elected a senator. After visiting Europe, he took a prominent part in the election of Lincoln. Organizing many schemes for the assistance of troops during the Civil War, Fish was also largely responsible for relief measures for the war prisoners. During 1869-77 he was a secretary of state under Grant. One of the commissioners for the treaty of Washington, he was identified with many negotiations which improved the relations between Great Britain and the U.S.A. He died Sept. 7, 1893.

**Fish Culture.** Increasing by artificial means stocks of fish for profit or pleasure. This ancient art takes many forms: breeding, feeding, aiding normal migrations, transplantation, introduction of new species, destruction of or protection against enemies. It is pursued with varying vigour in different parts of the world for widely different human needs. Nearly always it is fresh (sometimes brackish) water fishes which are concerned. A limited number of sea fish hatcheries are in operation, but so little is known of the causes of the immense natural fluctuations and of the conditions affecting the larval and post-larval stages of fish in the sea, that, even when astronomical numbers of eggs are handled, contributions by human effort can be of little significance.

When the fish can be controlled in ponds, lakes, and rivers, in almost every civilized country the state takes a hand proportional to national needs. Over fifty years a substantial literature has come into existence on the technique of fish culture. To the Chinese must be attributed the largest experience of an art probably stereotyped in China 1,000 years before the Christian era. A French writer has described the sight of

80 junks awaiting cargoes of fry for distribution, the average value of each cargo being £5,000. The valuable species readily cultivated are the carp, eel, and trout. In Germany, especially, the routine of draining and cultivating the bed of carp ponds is understood. There has long been a considerable trade in young eels for ponds and lakes. Early in the 20th century the German government, profiting by the new discoveries concerning the life history of the eel, established an elver collecting station on the Severn at Epney, whence during 1908-14 38,000,000 elvers were shipped to Germany via Grimsby.

Denmark has developed the culture of trout for food. Starting about 1890, some 100 trout farms in Jutland handle the fast-growing rainbow trout. Streamside ponds are constructed and the fish are fed on readily obtained sea fish refuse. The trout are sold when at a size suitable for serving singly in restaurants. From 1931 to 1936 the export averaged 628 tons annually, about one third being shipped to England. Over the same period 72,000,000 trout eggs were sold abroad, chiefly to Switzerland, France, and Belgium.

In Great Britain, where access to fish supplies from the sea is easy, the taste for fresh water species is both limited and local. The score or so fish farms in existence devote attention chiefly to trout. Results with salmon have not been convincing, but attention is given to the control of netting and pollution and the construction of fish passes to enable fish to reach their natural spawning areas. Success has attended the introduction of salmon and trout to New Zealand; while in the U.S.A. the cultivation of Pacific salmon is regularly undertaken.

In 1941, of the 5,878,000,000 eggs and fry of 45 different species handled, salmon and trout of eleven species were the principal group covered. In many parts of the world mountain streams have been populated by trout.

The service of aircraft has made possible the planting of fish in areas which might otherwise be inaccessible. A striking example of successful introduction of a new commercial fish to an area where it was unknown is afforded by the experience of the U.S. fish commission with the shad. In 1871 shad fry from the Hudson on the Atlantic coast were set out in the Sacramento flowing into

the Pacific. The young fish migrated to sea and the reappearance of mature fish ascending to spawn a few years later gave indications of the success of the experiment. The fish has now spread to rivers along 3,000 miles of coastline from California to Alaska. Experiments in northern waters with the plaice have demonstrated that this species can be transplanted from areas where it grows slowly to others where growth is rapid. The Danish government in cooperation with fishermen has engaged in a regular profitable business. The fish are carried in well vessels from the Jutland coast to the inner salt water broads. English authorities have carried similar small plaice from the nursery grounds on the Danish and Dutch coasts to the Dogger Bank, where the increase in growth has been found to be 300 or 400 p.c. The cultivation of certain shellfish, mussels in particular, has been practised with success for many years. Oysters can be relaid in areas suited to their growth; the experimental station at Conway has reared oysters up to the stage when they can be set out on the growing beds.

George T. Atkinson

**Fish Curing.** Term for various methods of preserving fish. The drying, pickling, smoking, or other curing of fish especially in times of abundance against periods of scarcity, is of great antiquity. Improvement in transport, development of cold storage and refrigeration, and of canning have gone far to reduce demand for the cured fish on which, until a few generations ago, man was partly dependent for maintaining his winter protein food stocks. However, in some places, by reason of the seasonal assembly of fish shoals, such as the autumn herring off Yarmouth, or the location of a far ranging fishing fleet such as that at Hull, Grimsby, or Aberdeen, extensive industries for the preparation of cured fish still operate.

Two types of fish are best suited for curing: the cod family, in which the fat is concentrated in the liver, can be salted and dried in the sun or by artificial heat; the herring family, on the other hand, with its fat dispersed through the body tissues, needs preservation in salt solution or by salting and smoking. In the former category, besides the cod itself there are the haddock, coal-fish, ling, whiting, and tusk. In the herring type are included

herring, pilchard, and sprat, and the shad and the anchovy.

**HERRING.** In Europe the herring outweighs all others in the commerce of cured fish. Long experience has taught not only the seasons of the coming of the shoals but also the periods of optimum condition for curing. For lighter cures for immediate use, e.g. kippers and bloaters, this is not of such importance as for the pickle cure in barrels. For instance, winter herrings, owing to their high water and low fat content, pine or shrink excessively in the salt solution. Early summer fish by reason of rich feeding tend to disintegrate in the barrel. The presence of milt or roe is also judged of great importance. The second half of the year furnishes the most satisfactory herrings for curing in barrels, marketed mainly along the Baltic seaboard; while fish most suitable for smoking for the centuries-old trade with the Mediterranean are those caught in Oct. and Nov.

Herrings for pickle curing are sprinkled with salt as soon as possible after discharge from the fishing vessel. At the curing yard they are again sprinkled in the farlanes or gutting troughs. From these, specially trained women, who follow the fishery along the coast, gut and pack. Each fish is seized with the left hand, and a deft movement with the short gutting knife held in the right hand removes in one operation the gills and gut: the milt or roe remains. Not only are the fish gutted at as high a rate as twenty in a minute, but they are also selected into the various trade categories for packing in separate barrels. The women work in crews of three, two gutting and one packing, their remuneration being by weekly wage plus an agreed amount for each barrel packed. It being found increasingly difficult to attract women to this work, experiments were begun with herring gutting machinery. Power-driven machines were also introduced for splitting herrings for kippers.

The packing of gutted herrings is done in orderly tiers, a layer of herring, a layer of salt, a layer of herring, and so on. Pickling begins immediately, the salt being dissolved by the natural juices of the herring. The room left in the barrel by the shrinking of the fish in this process is filled after a few days with other fish of the same cure. A hole is also bored in the bilge of the barrel, the pickle is

run off, and the space filled with more herrings; the barrel head is replaced and the pickle poured back through the bored hole, which is then closed with a bung. Stencilled on the end with the trade mark of the curer and the category of the contents, the barrel is ready for shipment or storage. Under certain strict conditions barrels of herrings receive a government brand.

#### Decline of the Trade

The changed face of Europe after the First Great War found the British herring industry deprived of its best customer, Russia; Germany and other countries on the Baltic were unable to purchase herrings to the extent they had done during the first decade of the century. Compared with an export of 8½ million cwt. in 1913, the average had fallen by the period 1933-1938 to under 2½ million cwt. A subsidy in 1919 and 1920 gave temporary stimulus, but successive crises led to legislation by which, under the Herring Industry Acts 1935 and 1938, the herring industry board was set up to reorganize, develop, and regulate the industry. For the period of the Second Great War, the board did not function, and matters affecting the herring came chiefly under the control of the ministry of Food. Recovery after the war of former markets in the Baltic Countries was slow.

Bismarck herrings and rollmops are pickled herrings further treated with white wine vinegar. Smoked herrings for export are cured almost exclusively in Yarmouth. Here, previous to a long period of smoking, suitable herrings are salted and stored in concrete vats. Export is principally to Italy and Greece.

The pilchard, rarely appearing in marketable quantities except off Cornwall, is by its perishable nature of little use except for curing. Salted and pressed in barrels, it is marketed in Italy. The catch fluctuates considerably and varied between 1,100 and 6,600 tons annually in the eleven years preceding the Second Great War.

Only at the time of its autumn migration to the coast is the sprat taken commercially. It lends itself readily to many curing processes. For immediate use it can be lightly salted and bloated or, by more intensive treatment with smoke, "redded." Both these are cold smoking methods. In special ovens the fish can be treated with hot smoke from hard wood chips, creating in a confined

space the highly prized *Kieler Sprotten*. Specially prepared sprat pickled with salt in barrels and with sugar and spices is in demand in Sweden, U.S.A., and S. Africa. The sprat catch in the eleven years before the Second Great War varied between 2,300 and 6,800 tons.

Mackerel is seldom cured in Great Britain; in some years Scandinavian vessels visit Scottish ports to cure in barrels mackerel taken in the nets of British fishermen in the course of summer fishing.

Cod. There is a demand for salted fish of the cod type in the Mediterranean countries, South America, and the W. Indies. Protective tariffs, fluctuating exchanges, movements towards self-sufficiency and improved fishing technique with up-to-date craft in the northern nations from off whose shores British trawlers had to bring their catches (Iceland, the Faroes, Norway), limited the development of British fish curing. The average annual exports of salt cod and haddock from Great Britain for the pre-war decade were 269,000 and 15,000 cwt. respectively. Other species are not separately distinguished in official statistics. Consult *The Art of Fish Curing*, R. S. Duthie, 1911; brochures of the Torry station of the department of Scientific and Industrial Research.

George T. Atkinson

**Fisher of KILVERSTONE, JOHN ARBUTHNOT FISHER, 1st BARON** (1841-1920). British sailor. Born

Russell

Jan. 25, 1841, at Rambodde, Ceylon, he entered the Royal Navy in 1854, and served in the Calcutta with the Baltic Fleet during the Crimean war. He was present at the capture of Canton in 1857 and the attack on the Peiho ports. He commanded the Inflexible at the bombardment of Alexandria in 1882, and later landed with the naval brigade, when he organized an armoured train. In 1899 he became c.-in.-c. in the Mediterranean.

Second sea lord at the Admiralty in 1902, Fisher was largely responsible for establishing the naval cadet colleges at Osborne and Dartmouth, which replaced the training ship *Britannia*. As first sea lord, 1904-10, he directed

great changes in naval organization, ships, and weapons, spurred on mainly by the competitive and rapid expansion of German naval power. He introduced the dreadnought and sponsored the development of oil fuel and submarines in the Royal Navy. He was made a peer in 1909. Upon the resignation of the marquess of Milford Haven in Oct., 1914, Fisher returned to the Admiralty as first sea lord.

There he energetically prosecuted the war at sea, and the decisive victory in the battle of the Falkland Islands (*q.v.*) on Dec. 8 was entirely due to his action in sending two battle cruisers secretly from the North Sea despite the opposition of the commanders in home waters. He strongly opposed the Dardanelles expedition, and in May, 1915, shortly after the offensive had been launched, resigned, maintaining that ships required by the Grand Fleet in the North Sea were being imperilled. Though publicly censured by the Dardanelles committee, he refused to defend himself. In 1919-20 he wrote letters to *The Times* criticising the conduct of naval operations during the war, notable for the refrain "sack the lot"; and in 1919 published his memoirs. He died July 10, 1920, being succeeded in the peerage by his son Cecil Vavasour Fisher (born July 16, 1868). A life of Lord Fisher was written by Adm. Sir R. H. Bacon, new ed., 1942.

**Fisher, ANDREW** (1862-1928). Australian politician. Born Aug. 29, 1862, at Kilmarnock, Scotland, he at first worked in the coal mines. In 1885 he emigrated to Queensland and in 1893 was elected to its legislature. Fisher entered the Commonwealth parliament as M.P. for Wide Bay in 1900. In 1904 he became minister of trade and customs, and in 1907 leader of the Labour party. He was thrice prime minister and during his administration of 1910-13 founded the Commonwealth Bank and began to build Canberra. He was high commissioner in England, 1915-21. He died Oct. 28, 1928.

**Fisher, GEOFFREY FRANCIS** (b. 1887). British ecclesiastic. Born May 5, 1887, he was educated at Marlborough and Exeter College, Oxford. An assistant master at Marlborough, 1911-14, he was ordained 1912, and was headmaster of Repton, 1914-32. Bishop of Chester in 1932, and transferred to London in 1939, he was appointed archbishop of Canterbury in succession to William Temple

in January, 1945, his enthronement taking place on April 19. For portrait see Archbishop.

**Fisher, HERBERT ALBERT LAURENS** (1865-1940). British historian and educationist. Born

H. A. L. FISHER,  
British historian

in London, March 21, 1865, he was educated at Winchester and New College, Oxford. As lecturer and tutor in history he remained at Oxford until 1912, when he became vice-chancellor of Sheffield university, a position he held until 1916. As president of the board of education in Lloyd George's cabinet, 1916-22, he was responsible for the comprehensive Education Act of 1918, providing a system of continuation schools and securing improved conditions for teaching. Warden of New College from 1925, he was a leading historian, his *History of Europe*, 1935, becoming a standard work. Other publications included *The Medieval Empire*, 1898; *Napoleonic Statesmanship*, 1903; *Political History of England, 1485-1558*, 1906; *Life of Lord Bryce*, 1926. Fisher died in London as the result of an accident, April 18, 1940.

**Fisher, IRVING** (1867-1947). U.S. economist. Born at Saugerties, N.Y., Feb. 27, 1867, he was educated at Yale, at which university he held a chair of political economy, 1898-1935. A member of many U.S. and foreign learned societies, he was a leading economist, and his numerous works, many translated into the chief European languages, included *The Nature of Capital and Income*, 1906; *How to Live*, 1915; *Stabilising the Dollar*, 1920; *The Money Illusion*, 1928; *The Noble Experiment*, 1930; *Booms and Depressions*, 1932; *Stable Money*, 1934; *World Maps and Globes*, 1944. He died April 23, 1947.

**Fisher, JOHN** (c. 1459-1535). English prelate and saint. Born at Beverley, he was educated at Cambridge, becoming master of Michail House in 1497 and chancellor of the university in 1504. In 1497 he had been appointed confessor to Henry VII's mother, Margaret,

John Fisher,  
English prelate  
After Holbein

countess of Richmond, and in 1503 became the first Lady Margaret professor of divinity. In 1504 he was made bishop of Rochester. He was a keen opponent of Henry VIII's divorce from Catherine of Aragon, was imprisoned in the Tower in 1534 for refusing to swear to the Act of Succession, and on June 22, 1535, was beheaded on Tower Hill for refusing to recognize Henry as supreme head of the Church. He had been created a cardinal on May 20. A zealous humanist, he was instrumental in bringing Erasmus to Cambridge. He was beatified on Dec. 9, 1886; and on the 400th anniversary of his death, 1935, he was canonised as S. John of Rochester. His festival is on June 22. A *Life* by N. M. Wilby appeared in 1929.

## FISHERIES: A VITAL FOOD INDUSTRY

*Further information will be found in the articles on various fishes used as food, e.g. Cod; Herring, etc.; on branches of the industry—Fish Curing; Trawling, etc.; and on the world's chief fishing grounds—Dogger Bank; White Sea, etc. See illus. facing p. 3377.*

In its widest sense, the term fisheries includes the taking of all kinds of water products and embraces the hunting of whales, seals, and other aquatic mammals, the taking of shrimps, crabs, lobsters, turtles, and alligators, and the gathering of pearls, sponges, and coral. In its more general application, however, the term is restricted to the taking of fish by line, net, or trawl.

Fishing, the earliest form of hunting, provided ancient man with his first flesh food, and trading in fish was one of the earliest forms of commerce. Specially built ponds have been found in which the ancient Egyptian and Chinese kept netted fish alive until they were purchased. The Romans maintained a large and profitable trade in lampreys and eels between the seaboard cities of Italy and the most distant parts of their empire, and fish was imported into Rome from places as far distant as the Caspian Sea. Until medieval times the Mediterranean was the principal fishing ground of the civilized world, but in the 17th century the European centre of the fishing industry moved to the N. countries, notably Britain, France, Norway, and Germany. Until the development of refrigeration in the 1880s, the consumption of fresh deep-sea fish was confined to coastal districts, and inland centres were restricted to salted fish or the limited supply of fresh water fish.

Salt water fish are classified as pelagic and demersal. The former

**Fisher, SIR (NORMAN FENWICK) WARREN** (1879-1948). British civil servant. Born Sept. 22, 1879, he was educated at Winchester and Hertford College, Oxford. He was private secretary to Sir Robert Chalmers, 1908-10; a special commissioner of income tax, 1910-13; on the national health insurance commission, 1912-13; deputy chairman of the board of inland revenue, 1914-18; chairman, 1918-19. He then succeeded Sir John Bradbury as permanent secretary of the treasury, a position he held until 1939. His signature succeeded that of Bradbury on British currency notes. During the Second Great War Fisher became a special commissioner for civil defence in London, 1940-42. He died Sept. 25, 1948.

group includes mackerel, herring, and a few other species which spend the greater part of their lives in mid-water, anywhere between the sea-bed and surface, according to their feeding and spawning habits. The great majority of edible fish fall in the demersal class (bottom fish), and with few exceptions they spend the greater part of their existence on or near the sea-beds. Although a few species of demersal fish come inshore for spawning or feeding, most of them spawn in the open sea, and shoals move over vast areas of water, either by swimming or with the aid of ocean currents. Cod, haddock, halibut, saithe, plaice, and other deep-sea fish feed very close to the bottom, where light, temperature, and movement are but little felt. Fast swimming fish, such as dog-fish and hake, come near the surface in search of food, but they rest and spawn on the sea-bed, and it is there that they are caught. Hake is essentially a deep-water fish and is normally caught at a depth of 350 fathoms, while cod is caught in bulk only on the fringe of the icefields in the Arctic circle. Of the demersal fishes cod is the most important, providing about half of the weight taken; among the pelagic, the herring predominates.

In normal times the most important European fisheries are those of Norway, and before the Second Great War Norwegian fishing fleets landed a total annual catch worth £10,000,000, mostly

cod and herring. The chief fisheries of Belgium are of the in-shore variety, and the shore fishing catch of France includes herring, mackerel, sardines, anchovies, and sprats. Before the Second Great War Germany had an extensive deep-sea and inshore fishing industry, the principal catches being cod, haddock, whiting, plaice, lemon sole, ling, and herring, which were landed at the North Sea and Baltic ports. Dutch fishing fleets are mainly concerned with the catching of flatfish, eels, herrings, and cod, which are marketed on the Continent and in Great Britain. Of the produce of the Portuguese, Spanish, and Italian fisheries, more than half is sardines.

In the western hemisphere are the great fisheries of N. America, extending from Labrador to Massachusetts. Seven years after Cabot discovered Newfoundland and reported upon its rich cod fisheries, France sent over her fishing fleets and paid bounties to encourage the industry. Other nations soon followed, and the Newfoundland cod fisheries have been responsible for more than one war between European powers. Icelandic waters now rival the Newfoundland banks for cod, and also yield great catches of haddock, ling, and halibut. By the use of ocean-going trawlers equipped with refrigerators, the British have fully exploited the Iceland fisheries and also developed extensive fisheries in the White Sea and the waters round Bear Island, far within the Arctic Circle.

#### Importance of the Herring

By far the most important fish commercially is the herring, and the largest catches are made by the fishing fleets of Norway, Sweden, France, and Great Britain, while this fishery is growing rapidly in Canada; herring constitutes 25 p.c. of the yield of all European fisheries.

Nearly every country with a seaboard has a fishing industry of some kind, and of recent years the West Indies, Australia, and New Zealand have developed a considerable export trade from their local fisheries. China, Japan, India, and Russia have large fishing industries, but the greater part of their catches is absorbed by home markets. Before the Second Great War, Japanese fishing fleets operated extensively off the American Pacific seaboard.

Of fresh water fish the most important is the salmon. The salmon of the American Pacific coast are caught when they are entering the

streams from the ocean to spawn. Both Canada and the U.S.A. have a vast export trade in canned salmon. Fresh water fish such as carp are bred in Central Europe, and various species of trout are raised in the hatcheries of Britain and the U.S.A.

**BRITISH FISHERIES.** The level of supplies, as seen in the accompanying table, shows no extreme variation from year to year, and has been maintained to an increasing extent by the proportion of the catch derived from the Arctic seas (Bear Island, Barents Sea, and

LANDINGS IN ENGLAND AND WALES

Years	Fish, excl. Shellfish cwt.	Value £	Shellfish Value £	Total value £
1928	13,444,000	13,184,000	429,000	13,613,000
1929	14,287,000	14,444,000	378,000	14,822,000
1930	15,678,000	14,143,000	378,000	14,521,000
1931	14,616,000	12,026,000	350,000	12,556,000
1932	13,756,000	11,318,000	352,000	11,670,000
1933	13,663,000	11,190,000	367,000	11,557,000
1934	13,575,000	11,960,000	397,000	12,357,000
1935	14,347,000	11,956,000	403,000	12,359,000
1936	15,813,000	11,931,000	444,000	12,375,000
1937	17,035,000	11,933,000	442,000	12,375,000
1938	15,533,000	12,233,000	409,000	12,642,000

Demersal fish are taken as to 97 p.c. by a net dragged over the sea bed (trawl or Danish seine). Lines to a limited extent in most European countries, except Norway, Iceland, and the Faroes, are used for both classes of fish. Trawling to any extent in the N. Sea began only about a century ago. Before the 1880s sail predominated. Trawlers visited the waters off Iceland in 1891, N. Russia in 1905, Spain and Morocco in 1906, and Newfoundland in 1911. From 1895, when the otter trawl replaced the beam trawl of the sail and early steam trawler, the capacity and efficiency of fishing gear were increased in many ways; greater depths and areas formerly considered unsuitable for trawling were explored and charted. In 1938 the British steam trawler fleet numbered about 1,400 vessels, of which 1,153 had their home ports in England and Wales. Of these 721 sailed from Grimsby and Hull, a number exceeding that of the rest of European countries combined. The two Humber ports accounted for nearly three-quarters of the trawl fish supply of the country.

Of some 4 million tons of fish landed in W. Europe in 1936, Norway and Gt. Britain were each responsible for about one quarter. Next in order with 569,000 tons came Germany, then France (275,000 tons), Iceland (261,000 tons), the Netherlands (160,000 tons), Sweden (110,000 tons), and Denmark (84,000 tons). Germany's special effort was towards supplying her own extensive need for herrings.

Iceland). The depressing effect of large quantities of low-grade fish was such that by mutual agreement the industry had to regulate production, and the Sea Fishing Industry Act, 1933, enforced a close season in certain N. waters during the summer. The changes which took place in ten years in the proportion of North Sea fish to that from the N. seas are indicated by the fact that, whereas between 1928 and 1938 the North Sea catch of demersal fish declined from 2,866,000 cwt. to 1,658,000 cwt., that from the principal northern fisheries rose from 3,763,000 cwt. to 8,427,000 cwt. Inshore fishing in Britain occupies many men. Small as their contribution is to the whole, it covers the most valuable fishes—salmon, trout, eels, and shellfish, including molluscs (oysters, mussels, cockles, crabs, lobsters, crayfish)—and pilchards and sprats.

In 1913 there were 15,000 vessels of all types manned by 80,000 men and boys engaged in the fishing fleets of Great Britain. Immediately following the First Great War, the industry suffered a serious decline in the face of subsidised foreign competition, and a system of quotas was established, but, although fishing revived considerably in the years immediately preceding the Second Great War, in 1938 it was little more than 70 p.c. of the figures for 1913; the number of vessels of all types had been reduced to 13,700 and the number of men employed as crews had declined to 56,000.

The plight of the once prosperous herring industry was the

major cause of the decline in the British industry. The control of herring affairs now falls to the herring industry board. It owes its origin to the first inquiries instituted by the sea fish commission appointed to recommend remedies for the depression which came over the herring industry in the world slump of the 1930s. Over a twenty-year period the export of herrings had fallen by 55 p.c. and home consumption by 45 p.c. The steam drifter fleet from which comes 80 p.c. of the herring catch decreased from 1,500 vessels in 1913 to 1,088 in 1933. The herring board found it necessary to reduce the fleet still further, and, by 1938 only 685 steam drifters remained. The contraction can be ascribed to the First Great War, which lost Britain her principal customers. In 1911-13 the average number of barrels exported to Germany, Russia, and the Baltic states was 2,424,000; in 1933 it was only 727,000 barrels. Parallel with this shrinkage, policies of self-sufficiency were developing: Germany's production increased from 251,000 in 1929 to 1,059,000 in 1937, and her volume of trawled herrings grew from 56,000 tons in 1930 to 163,000 in 1937; herring production on the N. Russian coast grew from 1,000 tons in 1930 to 99,000 tons in 1935. Further measures taken by the herring board aimed at tightening control over the quality of herrings exported, regulating the number of the nets and the areas fished, financing the purchase of fishing gear and the repair of vessels, and aiding research. The herring industry board resumed its work in 1946 after a wartime standstill during which many of the earlier problems became even more acute by reason of territorial and population changes in Europe.

#### Fisheries Convention for Europe

In the closing years of the 19th century, alarm was expressed in more than one country at the decline in the fish population, especially of the flatfish. Discussions led to the formation of the international council for the exploration of the sea, with headquarters at Copenhagen. An elaborate programme of research, interrupted by the First Great War, covering all matters affecting the sea and its inhabitants was entered upon. The outcome was prospective international legislation for the rational exploitation of European fisheries. In 1937 a fisheries convention was signed by the governments of Great

Britain, Belgium, Denmark, Germany, Iceland, Eire, the Netherlands, and Sweden. Amongst other things, the convention regulated the sizes of the meshes of otter trawls and seine nets to be used by vessels of the signatory countries in certain waters of the E. Atlantic. But for the outbreak of war in 1939, the convention would have been extended to provide for the replenishment of the fish population in the North Sea and eastern N. Atlantic.

#### Experiments in Re-Stocking

Fishermen have done little towards conservation or planning for their future supplies. There are several sea fish hatcheries in Europe, but their work is experimental only and, in view of the as yet little understood causes of the great fluctuations in the abundance of natural brood, cannot be regarded as contributing much to the stock. Oyster breeding, on the other hand, after some years of experiment, appears to be a commercial possibility. In Denmark fishermen cooperate with the government in transplanting young plaice from the coast, where they grow slowly, to the inner part of the Lim Fjord, where the growth in a season is so increased as to make the undertaking worth while on a commercial scale. English experiments have shown that similar results can be obtained by conveying small plaice from the inshore nursery grounds to the rich feeding grounds on the Dogger Bank in the middle of the North Sea where no small plaice are normally found. Important experiments in the acceleration of flatfish growth by adding artificial fertilisers to the water were carried out in Argyllshire lochs from 1944. But these enterprises are still experimental.

Cooperation of scientists and fishermen has produced systems of finding fish shoals by two methods: one is the adaptation of electronics as applied to the location of underwater objects such as submarines, the other by rapid assessment of areas with an abundance of microscopic plankton on which fish such as the herring feed. It is also possible to forecast with some accuracy prospects of fish harvests some time ahead. This has been done for herring, haddock, and cod, and is based on a study of the age composition of the shoals in one year and calculating subsequent mortality.

THE SECOND GREAT WAR. At the outbreak of the war, control over the movements of British

fishing vessels passed to the Admiralty, and as a result of security measures and the laying of minefields fishing was restricted to the grounds around Iceland, off the W. coast of Scotland, in the Irish Sea, and off the W. coast of Ireland. Large numbers of fishing vessels also were requisitioned for naval purposes (see Fishing Fleet). The amount of fish available during the war always fell far short of the demand, therefore, and Great Britain was obliged to draw largely upon supplies of frozen, salted, and tinned fish from Newfoundland, Canada, Alaska, and California. Further, many distant and neutral countries embarked upon campaigns to exploit their natural fishery resources. New Zealand developed an important industry in the canning of mullet and ling fish, while Australia greatly increased the yield from its domestic fisheries and established a government controlling body for the more orderly marketing of fish. Most of the S. American republics developed fishing industries for domestic consumption to replace the interrupted imports of food from abroad, and also established canneries for the supply of fish to the belligerent countries.

#### Wartime Fluctuations

Throughout the first year of the war in Europe, the U.S.A. fisheries greatly increased their yield of all kinds of fish, the bulk of the surplus being exported to neutral and Allied countries in Europe. With America's entry into the war, however, the requisitioning of many of the fishing industry's vessels caused a big drop in yield. In 1941 American fishing boats landed 2,500,000 tons of fish, but the following year the yield dropped to under 2,000,000 tons. Very limited fishing activities were conducted by Germany and the Axis-dominated countries of Norway, Denmark, and Finland.

Fishing was rehabilitated in the liberated parts of Italy under Allied control, and, following the Allied invasion of Europe in 1944, the French, and later the Dutch and Belgian, fishing industries began to revive. The North Sea grounds, however, continued to be greatly hampered by minefields. In 1945 the world's fisheries yielded a total catch of 14,000,000 tons; but in many countries fish continued in short supply owing to the dislocation of transport and other trade channels.

Owing to the relaxation during the war of measures designed to

maintain the fish population, there was over-fishing of certain areas, causing some concern regarding the future. Accordingly, the United Nations interim commission on food and agriculture established a sub-committee on fisheries to advise the commission on the preparation of a plan for international cooperation in the development and proper use of the world's fishery resources.

**Fisher's.** Island of the U.S.A. Situated at the E. end of Long Island Sound, 3 m. off Connecticut, it forms a part of Suffolk co., New York. It is about 8 m. long by 1 m. broad. It is frequented as a summer resort, and the chief occupation is agriculture. The U.S. government maintains a military and naval reservation, Fort Wright. Pop. about 400.

**Fishguard** OR ABERGWAEEN. Urban dist., seaport, and market town of Pembrokeshire, Wales. It stands on the Gwaen near its entrance into Fishguard Bay, 12½ m. N. of Havertfordwest. As the British Railways terminal port for Cork, Fishguard has an excellent harbour and a fine breakwater (2,500 ft.), a coastguard

By courtesy of S. Alcock & Co.

and sharpened before the wire is bent into shape. The shanks are then ringed or flattened, and the hooks are hardened, tempered, and scoured. Machinery performs the various processes automatically. Hooks vary greatly in size and shape, from the huge hook with swivel and chain attachment used for catching sharks, down to the tiny-eyed hook on which the smallest trout flies are dressed.

**Fishing.** Art or practice of catching fish. It is divided into two main branches. Sea fishing is done chiefly by men who work at it for a livelihood, and to whose efforts are due a considerable portion of the world's food supply. In this trawling plays an important part. The other branch is known more usually as angling, and is pursued mainly by amateurs for their own amusement, although in America great quantities of salmon are caught for food by professional fishermen. Fly-fishing is a form of angling.

The chief fish caught by the professional are the cod, herring, and mackerel; by the amateur, salmon and trout. Whale fishing, seal fishing, and pearl fishing are special branches.

Fishing is one of the oldest arts practised by man, and there is evidence that he did something of this kind 8,000 years ago. Various devices were employed and some of the earlier forms, made of stone and bronze, have been unearthed. Throughout the ages the existing varieties of rod, bait, and all the accessories were evolved. Close times are enforced by law, while a long series of Acts, which may be

said to date from Magna Carta, lay down the law for the U.K. Dealing with fisheries of every kind, deep sea, inshore, and inland water, they forbid the use of poison or explosives for the purpose of catching fish, make regulations about the registration and management of fishing boats, and lay down conditions for conserving supplies and using them in the interest of the nation.

For England and Wales the law is administered by the ministry of Agriculture and Fisheries while Scotland has its own department for the purpose. The United States, Canada, and other countries are equally vigilant in this matter. International agreements deal with areas, such as the Newfoundland banks and Bering Sea, where men of different nations meet. See Angling; Close Time; Fisheries; Fly Fishing; Trawling.

**Fishing Fleet.** Term used to describe a number of fishing vessels operating from a single home port, or vessels from different ports fishing in the same grounds. In a general sense it includes all vessels fishing under the same national flag; in Great Britain there are the Merchant Navy and Fishing Fleets. The latter includes not only steam and motor trawlers and drifters for deep-sea fishing, but also the longshoreman's yawl for line fishing in coastal waters. Grimsby, Lowestoft, Yarmouth, and Aberdeen all have large fishing fleets, consisting mainly of trawlers divided into three main groups: the small type, between 70-110 ft. long, which catch first-quality fish in home waters such as the North and Irish Seas; medium-sized vessels up to 140 ft. long, which fish the outer waters of the North Sea; and large trawlers of 130-180 ft. long, which go to Iceland, Bear Island, the White Sea, Greenland, and the Davis Straits. Equipped with radio, ice storage accommodation, and liver oil extractors, these vessels steam up to 5,000 miles during a voyage of 5-6 weeks and may bring home cargoes of 300 tons of fresh fish.

The largest individual fishing fleet in Great Britain is that engaged in netting herrings; in normal times over 800 drifters work from British ports during the herring season. Drifters vary

Fishguard. Bay of the Pembrokeshire port from which steamers cross daily to Eire

and lifeboat station, and a pier constructed by the G.W.R. in 1906. Slate is worked in the neighbourhood and fishing is an industry. There is normally steamer communication with Rosslare in co. Wexford, Eire. In 1797 Fishguard was invaded by some 1,200 French soldiers, who were forced to surrender to the local yeomanry. Market day, Thurs. Pop. 2,963.

**Fish Hook.** Apparatus for catching fish. At first a flake of flint sharpened at both ends, with a thong attached to the centre, was employed for this purpose. But the antiquity of the metal hook is great, bronze fish hooks of modern shape having been found in lake-dwellings in Switzerland and elsewhere.

The modern fish hook is made of soft cast steel wire. The wire is cut into lengths and the barb formed

between 50–100 ft. in length, and of recent years the tendency has been to fit them with motors instead of steam engines. The most notable fishing fleets outside Great Britain are the French ships which each year sail to Labrador for cod, and the Newfoundland motor dorries which operate off the Grand Banks.

During the Second Great War trawlers and drifters were requisitioned from the British fishing fleets for service with the Royal Navy as minesweepers, escort vessels, and patrol ships. In 1938, the British fishing fleets numbered 13,700 vessels aggregating 275,000 tons, of which 4,400 were sailing vessels and 9,300 steam and motor ships. The number of men and boys employed as crews was 56,000. The total losses suffered in the Second Great War, among vessels serving with the R.N. and those attacked in the fishing grounds, were 384 trawlers and 41 drifters.

**Fishing Rod.** Rod used by anglers. Its purpose is to cast the line and keep it clear of the bank or shore upon which the fisherman is standing, and it varies with the nature of the sport. Salmon fly rods, which are liable to great strain, are usually of cane with a steel rod in the centre, and measure from 16 ft. to 17 ft. 6 ins. For trout and other fresh-water fishing a lighter rod from 12 ft. to 13 ft. in length has been found the most suitable. Fishing rods are usually jointed in sections for greater convenience, and are fitted with a reel to wind in the line. See Angling.

**Fishkill.** Village of New York state, U.S.A., in Dutchess co., E. of the Hudson, 5 m. N.E. of Beacon. One of the oldest places in the state, it was settled by the Dutch and has two churches dating from the 18th century, one being the building in which the provincial convention of New York met in 1776, and in which deserters and spies were held during the Revolution. Cider making is the chief industry. Pop. 720.

Fishing Rod. Left, salmon rod and three joints; right, pike rod and joints

By courtesy of S. Alcock & Co.

**Fish Lice.** Small crustaceans of the order Copepoda (*g.v.*), which are parasitic on fishes. They depart widely from the typical forms of the order.

**Fish Measure.** Special measures of capacity used in the sale of fish. These can be summarised thus: 4 fish make 1 warp; 33 warps, a long hundred; 10 long hundreds, a long thousand; 10 long thousand (13,200 fish), a last. In addition to this 500 herrings make a code, 600 herrings a mease, and 615 herrings a maze; 37½ gallons of fresh herrings equal a cran, and 26½ gallons of cured herrings a barrel. A barrel of anchovies is 30 lb.

**Fishmongers' Company.** London city livery company. Founded to exercise a monopoly of the fish trade of London, and originally divided into two companies, Salt-fishmongers and Stock-fishmongers, its earliest extant charter is dated 1364, but the foundation fraternity of S. Peter existed in the 12th century. Sir William Walworth (*g.v.*) and Thomas Doggett (*g.v.*) were members; King George VI and the duke of Gloucester are freemen. The company examines all fish brought into Billingsgate. The hall in Upper Thames Street, E.C., was built in 1831–33, near the site of its two predecessors, the first of which was burnt in 1666 and rebuilt 1671. It was severely damaged by air raids in 1940. In it are shown Walworth's dagger, an embroidered Tudor pall, and a chair made from one of the original piles of old London Bridge.

Fishmongers' Company arms

**Fish Residues.** Fish offal suitable for manufacture into various by-products. The main products are fish meal, oils from the livers of fish, and oil and manure from the intestines. Fish meal is made chiefly from the head and bones; it is a valuable food for cattle and pigs. Medicinal

oil is principally the product of the livers of the cod and halibut. Other oil used in commerce and industry, especially in the process of tinning and in the manufacture of margarine and soap, is extracted from the livers and intestines of various fish. Fish manure is a valuable fertiliser, used particularly in the growing of beet.

The fish from which most of the waste material is obtained include herring, codfish, whiting, haddock, pilchard, and menhaden. A large amount of herring waste is obtained from the herrings prepared for curing, in which usually the head, the gills, and the viscera are rejected. In making kippers from herrings the gills and viscera are rejected. From the codfish the liver is always separated for the manufacture of cod-liver oil, the head, gills, viscera, and the backbone being used for by-products.

The industry is extensive in the U.S.A. and in Norway, but is still in its infancy in Great Britain, where in many fishing ports there is no provision for utilising the waste, which is emptied into the sea. Factories already exist, however, at Grimsby, Hull, Milford Haven, Falkirk, Montrose, Fraserburgh, Wick, and Aberdeen. The industry has received considerable stimulus from the shortage of the supplies of natural guano from Peru. Two kinds of fish guano are made, one from herring, the other from white fish. The former contains a large percentage of oil, which has to be extracted in the manufacture of guano, the product from the oily residues being a dark-coloured, soft fish guano. The product from the white fish is a dry, friable, light-coloured, more valuable guano. The value of fish guano depends upon its ascertained chemical analysis, the two most valuable constituents being phosphate of lime and nitrogen.

Cod-liver oil comes from the liver of that fish, the oil in white fish being accumulated in the liver instead of being scattered throughout the flesh, as it is in the herring. Hence the livers of the cod when caught are immediately separated, kept fresh, then broken up and allowed to ferment, after which they are cooked until the oil is free, and can be run off. A certain amount of stearine is present in this oil, and must be separated before the oil is used medicinally.

Sardine oil is obtained from the heads of the fish tinned in France and Spain. Menhaden oil, collected in the U.S.A., is used to make certain paints.

**Fiske, JOHN** (1842–1901). An American historian and philosopher. Born March 30, 1842, he was educated at Harvard, where he became lecturer on philosophy and assistant librarian. In philosophy, especially in Outlines of Cosmic Philosophy, 1874, he did much to popularise the evolutionist theory, combined with a belief in immortality, which he supported. His historical works cover most of the development of the U.S.A. from the earliest times to his day. He died July 4, 1901

*John Fiske*

**Fisk University.** An American educational institution. Founded in 1866 at Nashville, Tennessee, it is for the education of coloured persons and is named after Clinton B. Fisk (1828–90), an American soldier and philanthropist, who was active in its creation. The teaching given at Fisk is somewhat off the ordinary university lines. Money for its endowment was raised in Great Britain by the Jubilee Singers (*g.v.*), as they were called; coloured men also gave concerts, etc., for this purpose.

**Fission.** In atomic physics, the name given to the disintegration of the nuclei of some elements into two or more approximately equal fragments when exposed to bombardment by neutrons of the correct speed. While most elements when bombarded by neutrons (or other particles) divide sooner or later into an almost unchanged nucleus and a light particle such as a proton, a few elements, *e.g.* uranium and thorium, exhibit the phenomenon of fission which may be accompanied by a large release of nuclear energy. *See* Atom; Atomic Bomb.

**Fissurellidae** (late Lat., little fissures). Family of small limpets which have a hole at the apex or margin of the shell, whence their popular names, keyhole and slit limpets. Five species are found around the British coasts.

**Fistula** (Lat., pipe). Abnormal opening between a cavity in the body and the skin, or between two cavities in the body. For instance, a communication between the rectum and bladder is termed a recto-vesical fistula.

**Fit** (A.S. *fit*, struggle). Popular term for a sudden seizure, accompanied by loss of consciousness

with or without convulsions. *See* Convulsions; Epilepsy; Hysteria.

**Fitchburg.** City of Massachusetts, U.S.A., one of the co. seats of Worcester co. On a branch of Nashua river, 49 m. W. by N. of Boston, it is served by rlys. Settled 1719, it was incorporated 1764, and received a city charter 1872. Fitchburg manufactures textiles, clothing, shoes, paper, saws, guns, knives, and locks, and quarries granite. It has a high school known for the Fitchburg Plan originated in 1911, which established a cooperative system under which boys studying engineering divided their week between classes and work as paid apprentices in local industry. Pop. 41,824.

**Fitchée** (Fr. *fiché*, fixed). In heraldry a cross with a spike at its lower extremity is said to be fitchée or fitchy. It represents the proper cross of the old pilgrims and crusaders, which was stuck in the earth to improvise an altar.

**Fitchett, WILLIAM HENRY** (d. 1928). Australian author and journalist. Educated at Melbourne university, he entered the Methodist ministry. He edited the Melbourne Daily Telegraph and Southern Cross, and became principal of the Methodist Ladies' College. In 1897 his book, *Deeds that Won the Empire*, attained immediate success. His other works include *How England Saved Europe*, 1899; *Fights for the Flag*, 1900; *Wellington's Men*, 1900; *Nelson and his Captains*, 1902; *Wesley and his Century*, 1906; *The Tale of the Great Mutiny*, 1907. He died May 24, 1928.

**Fitter.** Term used in engineering to designate the workman who assembles parts of machinery and makes them fit. The work is highly skilled. The term is also applied in tailoring to one who takes measurements, and adjusts garments to fit their wearers.

Fitter is also a trade classification in the British army and the R.A.F. Army fitters attached to mechanical transport units are responsible for the upkeep of vehicles, and ordnance corps fitters are employed in the maintenance of guns and other weapons. In the R.A.F. there are fitters, engine; fitters, armourers; fitters, marine; and fitters, motor transport. These trades are among the most highly skilled and best paid.

**Fitz** (Lat. *filius*; Fr. *fil*s). Old Anglo-Norman word formerly split *fz* and meaning *son*. Like Scots Mac, Irish O', and Welsh ab, ap, it is prefixed to proper names to show parentage. Familiar ex-

amples are Fitzalan, Fitzgerald and Fitzwilliam. It is specially used to indicate natural sons of royal blood, *e.g.* Fitzjames, duke of Berwick, son of James II.

**Fitzgeorge.** Name taken by the three sons of the duke of Cambridge and his morganatic wife, Miss Louisa Fairbrother, the actress, whom he married in 1840. One of them, Sir Adolphus Augustus Frederick Fitzgeorge (1846–1922), entered the navy and retired as rear-admiral. In 1904 he was knighted. Another, Sir Augustus Charles Frederick Fitzgeorge (1847–1933), entered the Rifle Brigade in 1865 and later served in the 11th Hussars. He retired as a colonel and was knighted in 1904.

**Fitzgerald, LORD EDWARD** (1763–98). Irish rebel. Son of the 1st duke of Leinster, he joined the English army, served in Ireland, and in 1781 was wounded at the battle of Eutaw Springs in America. He was elected to the Irish parliament as member for Athy, afterwards

*Lord Edward Fitzgerald*

travelling in America, and in 1792 was cashiered for attending a revolutionist banquet in Paris. He joined the United Irishmen in 1796 and took an active part in the plans for the French invasion. The plot was discovered and Fitzgerald died in prison, June 4, 1798, from wounds inflicted by one of his captors. His wife Pamela was generally, but wrongly, believed to be a daughter of Madame de Genlis by Philippe Egalité, duke of Orleans. She was probably born in Newfoundland. She married Fitzgerald in 1792 and lived until Nov., 1831.

**FitzGerald, EDWARD** (1809–83). English poet and translator. He was born March 31, 1809, at Bredfield House, near Woodbridge,

Suffolk, the son of John Purcell, who assumed his father-in-law's name, FitzGerald, nine years after the poet's birth. Spending his boyhood abroad, he was sent, in 1821, to a school in Bury St. Edmunds, entering Trinity

College, Cambridge, five years later. He became intimate with Thackeray and Spedding; later with Tennyson and Carlyle. On leaving the university he spent a short time in France, but returning to Suffolk in 1831 never left it again, for more than a week or two, till his death, June 14, 1883.

His life, spent among books, flowers, and music, was that of a recluse; he began the study of Spanish in 1850, that of Persian in 1853. His world-famous translation of *The Rubáiyát of Omar Khayyam*, preceded in 1856 by an anonymous version of the *Sálámán and Absál of Jami* in Miltonic verse, was first published in Jan., 1859; but lay for months neglected, even by the translator's own friends, until Rossetti discovered it in the fourpenny box of a second-hand bookseller, and Swinburne proclaimed its genius to the world. A second, greatly revised, edition appeared in 1868, and its subsequent popularity has been phenomenal. FitzGerald also published *Euphranon*, a Platonic Dialogue, 1851; *Six Dramas of Calderon*, 1853; a version of the *Agamemnon*, 1876; two *Oedipus Tragedies*, 1880-81; and *Readings in Crabbe*, 1882. The dedication of Tennyson's *Tiresias* to "Old Fitz" advanced FitzGerald's personal reputation, but it was not till W. Aldis Wright brought out, in 1889, his *Letters and Literary Remains*, and, in 1895, his *Letters to Fanny Kemble*, that the world knew much of the man whose work it had long since taken to its heart.

He married, in middle life, Lucy, daughter of Bernard Barton, the Quaker poet, and the interest of his later years was centred in the sea, "knocking about somewhere outside of Lowestoft," as he puts it himself. He was a witty, picturesque, and sympathetic letter-writer, on terms of intimacy with the most interesting men and women of the day. His verse is tranquil and exquisite: the cultured expression of most attractive speculations.

**Bibliography.** *Letters and Literary Remains*, ed. W. A. Wright, new ed. 1902; *Letters to Fanny Kemble*, 1895; *Two Suffolk Friends*, F. H. Goorme, 1895; *Lives*, J. Glyde, 1900; *T. Wright*, 1904; *A. C. Benson*, 1905.

**Fitzgerald, Percy Hetherington** (1834-1925). Irish writer. Born in co. Louth, he went to Stonyhurst and Trinity College, Dublin. Called to the Irish bar, he became crown prosecutor, but abandoned law for literature. He contributed stories to Dickens's

*All the Year Round*, and produced a study of Dickens, whose friendship he enjoyed, and historical and theatrical works, also *Memoirs of an Author*. He engaged in sculpture as a hobby, and his statue of Dr. Johnson stands in London in the churchyard of S. Clement Danes. He died Nov. 24, 1925.

**Fitzherbert, Maria Anne** (1756-1837). Wife of George IV. A daughter of Walter Smythe, of Brambridge, Hampshire, she married in 1775 Edward Weld, of Lulworth Castle, Dorset. Her second husband was Thomas Fitzherbert, and after his death in 1781 she lived at Richmond. In 1785 she met the prince of Wales, who fell in love with her, but to avoid his attentions she went abroad. He pressed his suit, however, and the pair were married privately on Dec. 21, 1785.

According to the Royal Marriages Act, 1772, the union was illegal, and some, but not the prince, held that it was invalid; the lady being a Roman Catholic, it was sanctioned by the pope. In 1795 George married Caroline of Brunswick and Mrs. Fitzherbert left him for a time. They lived together again until 1803, when the prince began to tire of her. They finally parted, but George seemed to retain some affection for her to the end. Mrs. Fitzherbert, who had an allowance of £6,000 a year, died at Brighton, March 29, 1837. A box of papers was left by her to her executors for use at their discretion, but its contents were never fully examined. *Consult Mrs. Fitzherbert and George IV*, W. H. Wilkins, 1905.

**Fitzmaurice, Edmond George Fitzmaurice**, 1st Baron (1846-1935). British politician. Born June 19, 1846, second son of the 4th marquess of Lansdowne, he was educated at Eton and Trinity, Cambridge, and called to the bar in 1871. During 1869-85 he was M.P. for Calne. In 1880 he was commissioner for the reorganization of the European provinces of Turkey and Crete; in 1882-83, second plenipotentiary at the Danube conference in London. In 1882 he became under-secretary for foreign affairs in the Liberal ministry, but in 1885 lost his seat. Cricklade elected him in 1898 and

he retired in 1905. Again under-secretary for foreign affairs, he was made a peer in 1906. Lord Fitzmaurice wrote *Lives of the Earl of Shelburne* (1875-77) and *Earl Granville* (1905). He died without an heir, June 21, 1935.

**Fitzmaurice-Kelly, James** (1857-1923). British man of letters. Born in Glasgow, June 20, 1857, he devoted himself to the study of the language and literature of Spain. He was Taylorian lecturer at Oxford, 1902; Norman MacColl lecturer at Cambridge, 1908 and 1912; Gilmour professor of Spanish at Liverpool, 1909-16; and professor (Cervantes chair of Spanish) at King's College, London, 1916-20. His works include *Life of Cervantes*, 1892; *A History of Spanish Literature*, 1898; *Lope de Vega and the Spanish Drama*, 1902; *Editions of Cervantes in English*, 1901-03, and the *Oxford Book of Spanish Verse*. He died Nov. 30, 1923.

**Fitzpatrick, Sir Charles** (1853-1942). Canadian lawyer. Born in Quebec, Dec. 19, 1853, he was educated at St. Anne's college and Laval university there. In 1876 he became a barrister, and in 1879 crown prosecutor for Quebec. From 1890 to 1896 he was a member of the legislative assembly of Quebec. At the general election of 1896 Fitzpatrick entered dominion politics as member for the same city in the house of commons at Ottawa. That year he was solicitor-general under Laurier, and in 1902 became minister of justice. In 1906 he was chosen chief justice of Canada, retaining this post until made lieutenant-governor of Quebec in 1918. In 1907 he was knighted. During the years 1908-10 he was a member of the Hague tribunal. He died in June, 1942.

**Fitzroy.** River of Queensland, Australia. It is formed by the union of the Dawson with the Mackenzie, and takes an easterly course to discharge into Keppel Bay. It is navigable for steamers up to 1,000 tons to Rockhampton, a distance of 35 m. One of the most important rivers in Queensland, its fertile valley contains stock farms which supply the refrigerating works on the coast. Irrigation is practised by pumping from open water and from underground supplies.

Another river of this name in W. Australia rises in King Leopold range, and pursuing a generally westerly course empties into King Sound on the Indian Ocean. It is navigable for 100 of its 300 m,

Mrs. Fitzherbert,  
wife of George IV  
After R. Cosway

**Fitzroy.** North-eastern suburb of Melbourne, Victoria, Australia. It is a manufacturing centre, with a rly. station and several large recreation grounds, including the Edinburgh Gardens to the N.E., the Carlton Gardens to the S.W., and the Fitzroy Gardens to the S., laid out with fine avenues of trees.

**Fitzroy, SIR ALMERIC WILLIAM** (1851–1935). British public official. He was born Nov. 12, 1851, and went to Balliol College, Oxford. Entering the educational department of the privy council in 1876, he acted as secretary, and in 1898 was appointed clerk of the privy council, resigning in 1923. He was chairman of committees on physical deterioration, 1903–04; the Midwives Act, 1909; member of Royal Commission on venereal diseases, 1913–16; sat on the Dentists' Act committee, 1918–19. He was knighted in 1911. In 1921 he published a biography of Henry, duke of Grafton, in 1923 his own memoirs. He died May 31, 1935.

**Fitzroy, EDWARD ALGERNON** (1869–1943). British politician. Born July 24, 1869, son of the 3rd Lord Southampton, he was educated at Eton and Sandhurst, and joined the 1st Life Guards. He was Conservative M.P. for S. Northamptonshire (now Daventry division), 1900–06, and from 1910 continuously. He was deputy-chairman of committees, house of commons in 1922; and in 1928 he succeeded J. H. Whitley (*q.v.*) as Speaker. Fitzroy was the first soldier to be given this office, and the first to die holding it, as he did on March 3, 1943. His widow Muriel was granted the title of Viscountess Daventry.

**Fitzroy, ROBERT** (1805–65). A British sailor. Son of Lord Charles Fitzroy, he was born in Suffolk, July 5, 1805. He entered the R.N. College in 1819, and became lieutenant in 1824. In 1831–36 he sailed in command of the *Beagle*, a brig engaged in surveying the S. coast of S. America, with Charles Darwin as naturalist. In 1839 Fitzroy published his *Narrative of the Surveying Ships H.M.S. Adventure and Beagle*, in three volumes, the last written by Darwin. In 1841 he was M.P. for Durham, and in 1843 was appointed governor of New Zealand, but his attitude towards the settlers incurred their anger and he was recalled in 1845. He became vice-admiral in 1863 and died April 30, 1865. He is remembered by his Fitzroy barometer and for creating a system of storm warnings which developed into the daily weather forecast.

**Fitzroy's Cypress** (*Fitzroya patagonica*). Evergreen tree of the family Coniferae. A native of Patagonia, it has slender, spreading branches and flat, overlapping, oval-oblong leaves. The cones are small and star-shaped, consisting of nine scales. The height of the trunk is 100 ft.

**Fitzsimons, ROBERT** (1862–1917). British pugilist. Born at Helston, Cornwall, June 4, 1862, he went to New Zealand at the age of nine, and was trained as a blacksmith. He entered the ring as a professional, and moved to Sydney, where he beat Bill Slam, West, and Professor Hall, but was beaten by Jem Hall in the contest for middle-weight championship.

Proceeding to the United States in 1890, he defeated Jack Dempsey—to be distinguished from the later pugilist of the same name—in 13 rounds in the fight for the middleweight championship of the world; beat Peter Maher in 12 rounds; and in 1897 obtained the heavyweight championship at Carson City. In 1899, he was defeated by Jeffries, and in 1902, at 40, he challenged Jeffries again, to be beaten in the eighth round after putting up a splendid fight. In 1905 he was beaten by Jack O'Brien, and after meeting Jack Johnson and Bill Lang, he retired from the ring in 1912 after an exceptionally long career. "Bob" Fitzsimons died Oct. 22, 1917.

**Fitzwilliam, EARL.** A British title held by the family of Fitzwilliam since 1746. The family traces its descent from Sir William Fitzwilliam of Elmley, Yorkshire. It became specially prominent in the time of Elizabeth. Sir William (1526–1599), the grandson of a London merchant who was also a servant of Cardinal Wolsey, passed much of his time in Ireland as lord deputy, 1571–75 and 1588–94, and acquired lands there. His grandson was made an Irish baron in 1620.

William, the 3rd baron (1643–1719), was created a viscount and an earl in 1716. Another William was made baron (1742) and earl (1746) in the peerage of the U.K. He married Anne, daughter of the marquess of Rockingham, a union that brought Wentworth Woodhouse, near Rotherham, and large estates to the family. The 2nd earl, William Wentworth, is noticed separately (*v.i.*). In 1943 William (b. 1910) became 8th earl on the death of his father. The earl owns large estates in Yorkshire and Wicklow. When there is an eldest son he is called Viscount Milton.

**Fitzwilliam, WILLIAM WENTWORTH FITZWILLIAM, 2ND EARL** (1748–1833). A British statesman.

*Wentworth Fitzwilliam*  
After W. Owen

Born May 30, 1748, he succeeded the first earl in 1756. In 1782, on the death of his uncle, Lord Rockingham, he succeeded to the York-

shire estates of the Wentworths and added their name to his. He was president of the council in 1794, and in 1806–07. Lord-lieutenant of Ireland for a few months in 1795, he was recalled on expressing sympathy with Catholic emancipation. In 1798 he was appointed lord-lieutenant of the W. Riding of Yorkshire, but was dismissed in 1819 for censuring the Manchester magistrates over the incident called the Peterloo massacre. A life-long friend of C. J. Fox, Fitzwilliam died Feb. 8, 1833.

**Fitzwilliam House.** Institution at Cambridge University. Founded in 1869 to provide a cheaper education than that in the colleges, it was known until recently as the Non-Collegiate Students. A social and collegiate life developed so that today, except for lack of buildings, Fitzwilliam House offers the same life as the colleges. The present house was purchased in 1887. Administration is by a board appointed by the council of the senate. The board appoints the censor, who acts as senior tutor. Dining and the tutorial system are compulsory. Fitzwilliam House itself dates from 1727, and some parts may be even earlier; it was formerly called Halstead or Halsted House, having belonged to a family of that name. It is a pleasing example of the simple red brick architecture of the early 18th century.

**Fitzwilliam Museum.** Art and archaeological museum in Cambridge, founded in 1816 by Richard, 7th Viscount Fitzwilliam of Merrion, who bequeathed to the university his collections of pictures, drawings, prints, medieval MSS., books, etc., together with an endowment for the provision of an exhibition gallery. This was begun in 1837 from the designs of George Basevi and finished in 1874 from those of E. M. Barry. The pictures include works by Titian, Tintoretto, Veronese, Rubens,

Rembrandt, Hals, Gainsborough, Reynolds, Cézanne, Renoir, and Degas. 16th and 17th century masters and mezzotints of the 18th century are well represented in the print room. Among the MSS. are fine English, French, Italian, and Netherlandish examples. A collection of ceramics has a particularly fine English series and products of European factories and of the Near and Far East. The collection of coins is among the richest in Europe. Other departments are those of armour, textiles, Greek and Roman antiquities, and music. See Cambridge University illus.

**Fiume.** Seaport on the Adriatic. It stands on the river Rječina, at its outfall into the Bay of Quarnero, at the N.E. extremity of the Adriatic. It has several harbours—the Fiumara canal, used by coasting vessels; the Baross harbour; the main harbour, which is protected by a mole; and the free and petroleum harbours to the W. Virtually all the shipping trade of Hungary passed through its port, and the fisheries are of great importance. The town possesses distilleries, petroleum refineries, and mills, while there is trade in fruit, barrels, staves, furniture, tobacco, paper, chemicals, fertilisers, and soap. In architecture, the cathedral, the Roman triumphal arch, and the governor's residence may be mentioned. Under the Austro-Hungarian empire Fiume was a crown-land of Hungary, with an area of 8 sq. m. The pop. was largely Italian, but the suburb of Sushak across the river, and the surrounding area, were inhabited by Yugoslavs, chiefly Croats. Pop., pre-war, 53,896.

Fiume's mixed population of Italians, Croats, Magyars, and others made it a point of racial dispute. Long a small centre of coastwise trade, it came into prominence only when the Budapest-Zagreb-Fiume railway was built. Originally known as S. Vitus in Flumine, in 1465 it became a Hapsburg possession. Charles VI declared it a free port in 1717, and in 1776, by a decree of Maria Theresa, it was handed over to Croatia. In 1807 it was incorporated in Hungary. Two years later, under Napoleon, it became part of Illyria. In 1822 Fiume was restored to Hungary, but as a result of the Croatian national movement of 1848 was reunited to Croatia. In 1861 it was made autonomous. The Magyars favoured the Italian section of its inhabitants, and for nearly fifty years this union strove to prevent Slav predominance.

Fiume. View from the sea of this Adriatic port. It was ceded to Yugoslavia by Italy in 1947

After the First Great War possession of Fiume became a burning question. Though not assigned to Italy by the treaty of London (1915), it was claimed as Italian because it contained a majority of Italian-speaking inhabitants. The Croats, and on their behalf the new Serb-Croat-Slovene government, claimed it historically and on the ground that with Sushak it was inhabited by a majority of Southern Slavs.

The feeling between Yugoslavia and Italy as to its possession became more strained. Matters came to a head when on Sept. 11, 1919, Gabriele d'Annunzio (*g.v.*), at the head of the Italian volunteers, seized Fiume and set up a national council or provisional government. On Nov. 12, 1920, the treaty of Rapallo, signed by the representatives of Italy and Yugoslavia, established an independent state of Fiume which was to be slightly larger than the district formerly incorporated in Hungary. Insurgents denounced the treaty, and d'Annunzio declared that Fiume was in a state of war with Italy. The government of the latter expelled the insurgents. In 1924, by an agreement defining their relations in regard to the Adriatic, Fiume was annexed by Italy, while Baross harbour and the Delta were annexed by Yugoslavia. One of the four docks of Fiume was to be leased to Yugoslavia for 50 years in return for the yearly payment of a fixed sum; the railway station to be under a sort of international regime.

Marshal Tito's Yugoslav forces occupied Fiume (Yugoslav, Rijeka) on April 30, 1945. It was included in the territory ceded to Yugoslavia by Italy under the peace treaty of 1947.

**Five Knights' Case.** THE. Trial in the court of king's bench. Nov. 22, 1627. Sir Thomas Darnell, with four other knights, Corbet, Earl, Hampden, and Heveningham, had been committed to the Fleet prison in March by warrant signed only

by the attorney-general for refusing payment of the forced loan raised by Charles I. They applied for a writ of Habeas Corpus, demanding that the warden of the fleet should bring them before the court of king's bench and specify the cause of their committal.

The case came on for argument and the gaoler returned that they were imprisoned by the king's special command, *i.e.* for no stated offence; and the court, presided over by Chief Justice Hyde, decided, Nov. 28, that this was sufficient ground for committal. The prisoners did not deny the right of the crown to imprison in certain circumstances without showing cause, but pleaded that they were imprisoned for refusing to subscribe to the forced loan, of which they denied the legality. See Forced Loan.

**Five Members.** Specially, the five members of parliament whom Charles I tried to arrest, Jan. 4, 1642. Relations between crown and commons were strained when the king ordered the attorney-general to prepare articles of impeachment against the five: John Hampden, John Pym, Denzil Holles, Sir Arthur Hazlerigg, and William Strode. This was done, one of the charges being that of levying war against the king, and the house of lords was asked to order their arrest, a necessary preliminary to their trial before that body. This the peers refused to do, so the king went with the serjeant-at-arms to do it himself; with him were about 300 attendants.

He entered the house just as the warned members had escaped by river to the city, and asked the Speaker for them. Lenthall replied that he could only do as the house directed him, to which the king answered, "I see all the birds are flown." Next day Charles went to the city, but again he failed to secure the five. The impeachment was declared illegal. On Jan. 11 the members returned to

Westminster, a great concourse of people, both on the river and on the banks, cheering their arrival.

**Five Mile Act.** Act passed in 1665 which forbade those ministers who had been expelled from their livings in 1662 to reside within five miles of any corporate town or teaching in any school. They could obtain relief only by subscribing to the Act of Uniformity and taking an oath that resistance to the king was unlawful. The Act was part of the Clarendon Code, and became inoperative by lapse of time.

The name was applied also to an Act of 1593 by which popish recusants convicted of not going to church were forbidden to go more than five miles from home. Repealed in 1844, it had long been a dead letter.

**Five Nations.** Name given to the Indian nation of the Iroquois, because it consisted of five tribes. These were Mohawks, Oneidas, Cayugas, Onondayas, and Senecas. Early in the 18th century they were joined by the Tuscaroras and were known as the Six Nations. (See Iroquois.) It is also the name of a volume of poems by Kipling, the five nations being the chief members of the British Empire.

**Fives.** Game of handball. It is played either with the bare hand or with gloves, though at the present time almost invariably with the

latter. The derivation of the word fives is doubtful, although various suggestions have been made that it is so called from the five fingers of the hand, or that it was played by five people on each side.

Fives was popular early in the 19th century, when it was played in closed spaces especially built for the purpose, and also in tennis courts. One of the most famous fives courts was in S. Martin-in-the-Fields, and there is an old print representing fives in the tennis court in Leicester Fields, which gives some idea of the game as then played. A feature was that the ball was bounced on the ground, and then struck with the hand for the service. The ball nowadays is thrown up so that it touches first the back wall and then a side wall before the receiver hits it. William Hazlitt's obituary of John Cavanagh, the Fives Player, which appeared in *The Examiner*, is the best-known piece in the literature of the game.

In modern days fives is played chiefly in three forms of court, one being the Eton. The court, unique in several features, originated from part of the chapel at Eton against which the game used to be played. A buttress and some of the chapel steps gave rise to the present hazards in the court which afford so much interest and variety to the

game. The court has three walls, and not long ago all courts were uncovered. Now there are a few courts covered by a pent-house roof. The game needs four players, and demands the highest skill and quickness of movement.

A Rugby fives court, called after the school of that name, is a four-walled building covered with a roof. The walls are all plain, except that on the front wall there is a ledge or board, above which the ball must be struck to be in play. The game is played at most public schools; the rules were revised and brought up to date in 1913. Winchester fives is similar to the Rugby game, except that in the left-hand side wall of the court there is a projecting buttress which forms a hazard. Courts of this kind exist only in one or two places outside Winchester. Like the Rugby game, it can be played by one or two players a side. The service is given by one player throwing the ball on to the wall. His adversary can refuse any service, but if he does not refuse it, he must hit the ball on to the right-hand side wall, and then on to the front wall above the ledge or line.

In all varieties, after the rules of service have been complied with, the game proceeds by rallies, i.e. the ball is returned on the volley or after one bounce and must go above the ledge. The player who first fails to do this loses the rally, and either yields the service to another player or, if he was the receiver, loses a point. A game consists of 15 points. The ball is made like a rackets ball. The foundation is of cloth, bound tightly round with twine and covered with white kid. The weight of the ball in Eton fives is 1½ oz. and in Rugby 1¼ oz. Apart from its vogue in public schools, the game is popular in the north of England, specially prepared courts or alleys being in use in co. Durham.

**Five Towns, THE.** Name given in various novels by Arnold Bennett (*q.v.*), a native of the district, to the towns of the Potteries district of Staffordshire. In reality there were six separate towns—Stoke-upon-Trent, Hanley, Burslem, Tunstall, Longton, and Fenton—federated in 1910 into one administrative co. borough which became the city of Stoke-on-Trent (*q.v.*) in 1930. Bennett's five were thinly disguised as Knype, Hanbridge, Bursley, Longshaw, and Turnhill; and he extended the topographical analogy in other details, e.g. Waterloo Road, from Burslem to Coat-

Fives. An Eton game in progress, illustrating the construction of the court. Inset, about to volley for the pepper-box

bridge, became Trafalgar Road, from Bursley to Bleakridge. Novels introducing the Five Towns include *The Old Wives' Tale*, Clayhanger, *Hilda Lessways*, *These Twain*, *The Card*, Whom God Hath Joined, *Anna of the F.T.*, *Leonora*, and *Helen with the High Hand*; there are also three volumes of short stories, *Tales of the F.T.*, *The Matador of the F.T.*, and *The Grim Smile of the F.T.*

**Five Year Plans.** Economic programmes of the Soviet Union. The first plan, 1927-32, provided for the creation of basic industries and was initiated by a central planning office. The second, 1932-37, and third, 1937-42, dealt mainly with the processing industries and the production of articles for the home market. The fourth plan, 1946-50 inclusive, had as its objectives the rehabilitation of war-devastated districts, the restoration of industry and agriculture, and the surpassing of the pre-war level of production.

The first three programmes were fulfilled in the main, but at the cost of great privation inflicted on the population and the retention of a low standard of living. By 1938 industrial production was nine times greater than in 1913; but agricultural developments were not in proportion, the peasants having destroyed large numbers of stock and wasted grain in face of forced collectivisation. The five year plans were based on the principle that the Soviet Union must be self-sufficient, foreign trade being taken into account only where the acquisition of foreign currency was necessary. The fourth programme called for an increase in industrial output of 48 p.c. as compared with 1940, in farm produce of 27 p.c. Each republic was allotted a "target" figure for its industries and a capital sum for the execution of its task.

The development of the iron and steel centres of the Urals, Siberia, and the Far East continued; new mines and plants expanded the non-ferrous metal industry, especially in Central Asia, N. Urals, and E. Siberia. New mines were projected in the Moscow and Pechora coalfields, and vastly increased production was expected from the Kuznetsk basin, Urals, Ukraine, Caucasus, and Central Asia. Maximum development of petroleum extraction and refining was ordered in the east as well as in the Ukraine. Thirty hydro-electric stations were to be erected; and by 1950 the pro-

duction of synthetic rubber was to be doubled; more cotton was to come from Siberia and Central Asia. The construction of 4,500 m. of new rly. track was called for, including the Stalinsk-Magnitogorsk line. The Stalin White Sea-Baltic canal was to be rebuilt and the Mariinsk waterways constructed, the mercantile fleet to rise by 600,000 tons by 1950. Air lines were to connect Moscow with the capitals of the constituent republics.

**Fixation.** Term used in psychology to denote the arrest of an instinct during its growth at some point short of maturity, with the result that the emotions which should accompany the functioning of the instinct retain or regress to a childish form. A mother-fixed man seeks in all his love objects the mother who gives all and asks little or nothing in return. *Consult Psycho-Analysis*, E. Glover, 1939.

**Fixed Oils.** Term used by the old alchemists and still current in pharmacy. They constitute a homogeneous group of oils present in animal and vegetable organisms. Olive oil, almond oil, linseed oil, castor oil, have been known from earliest times and valued for their emollient and other properties when used externally. Cod liver oil and castor oil have long enjoyed reputations for their medicinal properties. All members of the group are more generally described under *Fatty Oils*.

**Fixture** (Lat. *figere*, to fix). Term used in English law for a thing of a chattel nature which is affixed to the freehold, so as to become part of it, and, therefore, to become realty and not personalty. Sometimes these things can be removed again by the people who put them there, so that they become personal property again, and sometimes not. Practically, questions about fixtures become important as between landlord and tenant, between the devisee and the personal representative of a deceased, and between the representative of the owner of a particular estate, e.g. a tenant for life, and the ultimate owner. In the second case the devisee is entitled to all fixtures, but in the third the personal representative may remove those put up for ornament or trade if he can do so easily.

As between landlord and tenant the right of removal is stronger. A tenant is entitled to remove all fixtures put up by him for ornament or convenience which can be removed without much damage to the premises, e.g. marble mantel-

pieces, pier-glasses, tapestry, grates, etc., or cupboards fixed in hold-fasts. The tenant may remove trade fixtures unless in so doing he causes serious damage to the property. Similarly agricultural fixtures can be removed, but the tenant must make good any damage he does. A tenant must remove his fixtures before his tenancy expires—he cannot go back afterwards and take them away. If he leaves them behind he has no claim to them, or to compensation for them, as many people suppose; nor can he demand that a succeeding tenant shall pay for them. They are the landlord's property. *See Landlord; Tenant*.

**Fizeau's Experiment.** This experiment was made by A. H. L. Fizeau (1819-96) to determine the velocity of light. The apparatus consisted of a toothed wheel, which was made to revolve at a definite speed. The teeth of the wheel cut off the view from a light when a certain speed was reached, and enabled calculations to be made of the time taken for the light to travel from its source to a distant mirror and back again. *See Light*.

**Flaccus.** Name of a well-known Roman family, the following members of which deserve mention: (1) Quintus Fulvius, Roman general in the second Punic War. Together with his colleague, Appius Claudius Pulcher, he captured Capua in 212. (2) Marcus Fulvius, one of the commissioners appointed to carry out the agrarian measures of Tiberius Gracchus, who met his death, with Gaius Gracchus, in 121. (3) Marcus Verrius, a grammarian in the reign of Augustus, the author of a work on the Meaning of Words, abridged by Festus (*q.v.*). The poets Horace and Valerius also belonged to the family. *See Horace; Valerius*.

**Flacius** or **VLACICH**, MATTHIAS (1520-75). Lutheran divine. Born at Albona, Illyria, March 3, 1520,

Matthias Flacius,  
Lutheran divine

he studied languages in Venice, and theology at Basel, Augsburg, and Wittenberg, where he came under the influence of Luther and Melancthon, and was appointed professor of Hebrew in 1554. Henceforth he was involved in a series of controversies, siding with Luther against Melancthon. He settled in turn at Magdeburg, Jena,

where he was professor of theology, Ratisbon, Antwerp, Strasbourg, and Frankfort-on-the-Main, where he died in poverty, March 11, 1575.

One of the charges against Flacius was that of Manichaeism, based on his statement that sin was inherent in human nature from the Fall. The work in which this appeared, *Clavis Scripturae Sacrae* (Key to Holy Scripture), 1567, formed the basis of biblical hermeneutics, a term defining the principles and laws governing biblical interpretation as distinguished from exegesis (*q.v.*). Other works of Flacius replied to the Roman objection to the Reformation as a mere innovation, and traced Church history from an evangelical standpoint.

**Flag** (*Iris*). A large genus of perennial herbs. Of the family Iridaceae, they are natives of the N. temperate regions. The species form two groups: one in which the rush-like foliage dies down each autumn, and the life of the plant is continued by a long

bulb-like rootstock; the other in which the thick, sword-shaped leaves arise

from stout, slightly creeping rhizomes. The term flag is generally applied to members of the second group, the others being spoken of by the name *Iris* (*q.v.*). The leaves enfold each other at the base, and from their midst rises the flower stem, bearing the large brightly coloured flowers. There are three sepals and three petals, the sepals much larger than the petals, and the stamens expanded to look like petals. The yellow flag (*I. pseudacorus*) is common in ditches and marshes. The blue flag (*I. germanica*), so common in gardens, is wild in S. and Central Europe. The seed vessel is a large, leathery

**Flag.** Yellow Flag, *Iris pseudacorus*, showing the tall sword-like leaves; top, flower of *Iris foetidissima*

capsule, splitting when ripe into three pod-like divisions, packed with large flattened seeds.

**Flag.** A sheet of stuff, particularly coloured, or of a single colour, plain or bearing symbols, and flown from a staff or halyard. Flags may be national or personal. They were known to the ancients, though the standard or symbol placed on the top of a staff, like the Roman eagles, was more common. This was followed by the gonfalon type, and then by the guidon, a small piece of stuff attached to a lance. In mediæval days the shapes and sizes of flags were diverse, but were soon strictly regulated. The standard was a large and long flag, often with one, two, or more points, parti-coloured and decorated with crests, badges, and devices. The banner was large and square, or rectangular, emblazoned with armorial devices, and denoted that the bearer was entitled to levy and lead troops.

The standard with one point was known as the guidehomme (abbreviated into guidon); the ancient was a small guidon; the pennon (bearing badges and motto only) was half the size of the guidon, and had one tail; the pendant was the ship's guidon; the pennoncelle or pencil, a small pennon, attached to a lance and usually bearing a single heraldic symbol; the pavon was a triangle, with horizontal base, the banderolle a long narrow flag or streamer, such as the modern pennant.

National flags evolved slowly. The English white flag with the red cross of S. George appears to have been introduced by Richard I on his return from the East, but it long appeared side by side with many others, including the royal armorial banner. The British national flag is the Union Jack (*q.v.*). The white ensign, consisting of the red cross of S. George and the union flag in the jack, or upper left quarter, may be worn only by ships of the Royal Navy and yachts of the Royal Yacht Squadron. The blue ensign is the flag of the Royal Naval Reserve, worn only by merchant ships whose commanders and a certain proportion of the crew are members. Subject to conditions, 37 British yacht clubs are entitled to the blue ensign, and 32 to the blue ensign defaced with the club badge. Defaced with crossed swords in the fly, the blue ensign is worn by ships operated by the War office. The red ensign, which has

a Union flag in the jack, is the flag of the merchant navy and may be worn by six British yacht clubs, provided it is defaced with the club badge.

Yacht clubs entitled to fly the blue or red ensigns must have an Admiralty permit, the issue of which depends upon strict conditions. The yacht must be registered at a British port and owned by a British subject belonging to one of the clubs recognized in the Navy List. Warrants are granted only to yachts used for cruising, and should a yacht be turned to commercial purposes the permit is at once withdrawn. Admiralty regulations prohibit the wearing of ensigns without warrant on the Upper Thames, the Norfolk Broads, or Cumberland lakes, or any other tidal waters, rivers, lakes, or inland waters.

By the Merchant Shipping Act of 1894, no British merchant ship may fly at the stern any flag except the red ensign, unless her master is entitled to the blue ensign. In no circumstances may either ensign carry a house-badge or other distinctive mark. Most British dominion and colonial flags consist of the blue or red ensigns with a Union flag in the jack and national emblems or shields in the centre or fly. Regimental flags have a field the colour of the regimental facings, and the regiment's badge and battle-honours in the centre. See Colours, Ensign.

**Flagellants** (Lat. *flagellum*, little whip). Name given to various ascetic bodies in the R.C. Church whose adherents practised flogging themselves or one another as a means of disciplining the flesh and promoting spiritual growth. They arose in Italy in the 13th century, and continued to break out sporadically for about 150 years. One of their chief leaders was Cardinal Peter Damiani, who taught that a vigorous scourging was worth many years of ordinary self-denial and mortification. In 1260 there was a great outbreak of this form of fanaticism at Perugia, and in the following century it caused trouble in Germany and Hungary.

When the Black Death swept over Europe in 1348, the Flagellants had a great revival, and held processions through the streets stripped to the waist and singing penitential psalms. A halt was called at intervals, and all scourged one another in turn. About 120 of these enthusiasts reached London,

but won no followers in England. They were denounced by Pope Clement VI, and finally suppressed by the Inquisition.

**Flagellata** or **MASTIGOPHORA**. Sub-division of the protozoa. Found in stagnant water, they have "whiplike" threads of protoplasm which by their lashing movements propel the animal through the water.

**Flagellum**. A filamentous protoplasmic outgrowth arising singly or among a few of its kind from the surface of a cell in which a basal granule occurs near the point of attachment. The reciprocating or spiral movement of a flagellum, unlike that of a cilium, is independent of the motion of any other structure of the same kind which may be present, but similarly induces relative or actual movement in the liquid into which it projects. Both flagella and cilia may possibly be sensitive to contact stimuli.

**Flageolet** (Fr.). Wind instrument of flute tone, played vertically through a mouth-tube. The modern instrument has a separate mouthpiece, but those of the 17th century had the blowing hole on a sloped end of the main tube, like the present-day penny whistle. The true 17th century flageolet had two of its six finger-holes at the back; these were governed by the player's thumbs. See Recorder.

**Flag Lieutenant**. Lieutenant in the Royal Navy appointed to act as aide-de-camp to an admiral, and usually a specialist in signalling. His insignia consists of the aiguillette or golden cord on his left breast.

**Flag Officer**. Naval officer of the rank of rear-admiral or above who is entitled to hoist a flag on board ship to denote his command. There are four grades of flag

officer in the Royal Navy: rear-admiral, vice-admiral, admiral, and admiral of the fleet. The flags are: rear-admiral's, S. George's cross with two red balls, flown at the mizzen; vice-admiral's, S. George's cross with one red ball, flown at the foremast; admiral's, S. George's cross, flown at the mainmast; and admiral of the fleet, Union Jack. They are derived from the banners which were flown on board ship in the days when generals held the principal commands at sea. A commodore or other senior officer below the rank of rear-admiral flies a pennant or burgee when in command of a squadron.

**Flagship**. Vessel in which a flag officer is accommodated, and in which he flies a distinctive flag to indicate the ship to which others must look for signals. A single fleet may have many flagships, according to the number of its tactical units. The tactical unit is a division of four ships, usually with a rear-admiral in command; and two divisions make a squadron, over which is a vice-admiral, who also has charge of one of the two divisions. A number of battle squadrons, with their attendant craft, make up a fleet, the commander-in-chief, as a rule, flying his flag in a vessel which is outside the divisional formation, and at liberty to place herself where she chooses.

At the principal home naval stations the flag of the local commander-in-chief is flown in an old warship, i.e. the Victory at Portsmouth, the Impregnable at Devonport, the Pembroke at Chatham, and the Crescent at Rosyth, but the officer lives in an official residence ashore. Most of the senior departmental officers in flagships, i.e. those chosen for staff, gunnery, torpedo, navigation, or engineering duties, receive a special flag allowance in addition to their pay. Vessels that are not flagships are sometimes called private ships. See Battleship; Navy.

**Flagstaff**. City of Arizona, U.S.A., the co. seat of Coconino co. Situated at an altitude of 6,907 ft., it is on the main line of the Atchison, Topeka, and Santa Fé rly. and has an airport. It is in an area of national parks, forests, and monuments, Indian reservations, and sheep and cattle ranches, and is the centre for tourists visiting the Grand Canyon, Painted Desert, Petrified Forest, etc. Flagstaff trades in livestock and lumber. Dry farming is carried out in the surrounding

country. First settled by white men in 1876, it was incorporated as a city in 1928. Pop. 5,080, including Indians, Mexicans, and Negroes.

**Flagstone**. Fine-grained argillaceous sandstone, which splits easily in slabby fashion along the bedding plane. Fine sandstones which do not show this so-called lamination are sometimes included under the same name. Flagstones are composed mainly of minute grains of quartz, but generally contain also some feldspathic and micaceous material. The colour of flags varies from almost white to grey or yellow; while the mica flakes, if present, give the stone a sparkling appearance in the sunlight. Their fine, even texture, their strength, and the readiness with which they break into blocks of convenient size make them suitable for use as building stones.

Flagstones are mainly used, however, for paving-stones, kerbstones, hearths, sills, and steps, and those varieties which split into very thin layers, for roofing.

**Flaherty**, ROBERT JOSEPH (b. 1884). American film director. Educated at Upper Canada College, Toronto, he led four expeditions into subarctic eastern Canada, explored and mapped the archipelago known as Belcher Islands, Hudson Bay, and also the unknown lands of N. Ungava. In 1920 he entered the film industry, later producing *Nanook of the North*, a picture dealing with the Eskimos of Hudson Bay. Then he made *Moana*, a study of the Samoan Islands. His finest films included *Tabu* (1929-31); *Man of Aran* (1932-34); *Elephant Boy* (1935); *The Land* (1939-41), this being made for the U.S. department of agriculture.

**Flak** (German *Fliegerabwehrkanone*, cannon against aircraft, giving the initials F.L.A.K.). Anti-aircraft fire; specifically, the actual projectile and its fragmentation after exploding. During the Second Great War the term flak was at first used by R.A.F. crews in reference to "flaming onions," German incendiary shells fired in bursts and resembling a string of onions. Later the word indicated any A.A. barrage, whether friendly or hostile.

A flak ship was a small German craft of the coastal or trawler type mounting anti-aircraft guns, used in the Second Great War for the protection of small coastal convoys or of ships in harbour.

A flak tower (Ger. *Flakturm*) was a concrete tower mounting heavy

Flageolet. Left, 17th century instrument; the open circle shows thumb position at back of tube. Right, modern flageolet with four keys

and light A.A. guns, built by the Germans for the defence of cities and other specific targets. Some flak towers in Berlin were over 100 ft. high and had at their base public air-raid shelters. Similar towers, but constructed of steel and mounted on caissons, were set up in the Thames estuary for the protection of ships assembling for convoy. These mounted heavy and light A.A. artillery and were jointly manned by the Royal Navy and the Royal Artillery. They were grouped in fives, being connected by catwalks.

**Flail** (Lat. *flagellum*, little whip). A hand implement for threshing. It is now little used, except on a small scale for flax or when separating peas and beans for seed purposes. It consists of a shaft or handle, commonly made of ash, and a swingle (swiple) of some hard, non-splitting wood. The two are fixed together so that the swingle can move freely, this being effected either by leather thongs or by interlocking an ash swivel on the shaft with a leather loop on the swingle. See Agriculture; Threshing.

**Flambard**, RANULF OR RALPH (d. 1128). The chief minister of William Rufus. Son of a Norman priest, he was made chaplain to the bishop of London, and after William II's accession became his principal adviser, especially in financial matters. In 1099 he was made bishop of Durham. He incurred unpopularity by his extortionate fiscal methods, and after the death of Rufus was imprisoned, but escaped to Normandy, where he became bishop of Lisieux. He returned to England in 1106, after the battle of Tinchebrai.

**Flamborough Head**. A promontory on the E. coast of Yorkshire, England, forming the N. arm of Brdlington Bay. The chalk cliffs, rising to 450 ft., are pierced by a number of caves, and the action of the sea has fashioned the rocks into fantastic shapes. The cliffs are a breeding place for innumerable sea birds, and the collection of eggs in late May and early June is a traditional and perilous local industry, especially in the neighbourhood of Speeton and Bampton, to the N. The lighthouse is 214 ft. above sea level,

Flamborough Head. Promontory on the E. Yorks coast, with chalk cliffs rising to 450 ft.

and its revolving light is visible for 21 m. Flamborough village, largely inhabited by fishermen, is some miles inland. The neighbourhood of the lighthouse has been greatly marred by the indiscriminate building of small houses and bungalows.

**Flamboyant** (Fr., flaming). In architecture, a development of late French Gothic. It owes its name to the flame-shaped openings in tracery which were its chief characteristic. The period of Flamboyant was the late 15th and early 16th centuries. The style hardly penetrated to Great Britain, though some of the flowing tracery in Chester cathedral approximates to it. Among French examples are the church of S. Maclou at Rouen, and part of Tours cathedral.

**Flame**. Gaseous matter raised to a temperature at which it becomes self-luminous, as a result of combustion. Some gases inflame spontaneously because the ignition temperature is as low as the ordinary temperature of the air. Examples are cacodyl, phosphorus dihydride, and zinc ethyl. As a rule, however, the temperature of the gas must be raised before the chemical reaction with the oxygen of the atmosphere takes place. An agency which lowers the temperature below ignition point puts out the flame: a copper helix placed in a candle flame extracts heat so rapidly that the flame is extinguished.

This cooling action is used in the Davy miners' safety lamp, where the wire gauze prevents the flame from being communicated to the inflammable fire-damp in the mine. It has long been known that ordinary flames are hollow and that

there are "solid" flames where the complex molecule of a gas is by combustion broken up into simpler forms, e.g. in burning nitrogen trichloride. Berzelius pointed out that a candle or hydrocarbon flame shows four distinct regions: (1) the dark central region, (2) the yellow region, (3) the blue region, and (4) the faintly luminous portion. The dark portion consists of unburnt gases, whilst the yellow portion occupying the greatest part of the flame is the luminous portion.

The temperature of a flame depends upon the heats of combination of the constituents and the specific heats of the products of the combination. The temperature of sulphur burning in air is comparatively low, whereas an oxy-acetylene flame reaches 2,500° C. Oxidation of substances like phosphorus may give rise to chemiluminescence at low temperatures, and thus to cool flames. The colour of a flame is not as a rule indicative of the calorific power. The yellow gas flame is converted into a hotter non-luminous flame by the admixture of air, such burners, known as Bunsen burners, being used for heating operations in the laboratory and the kitchen.

A sensitive flame is a gas flame produced by a pin-hole burner in which the pressure of the gas has been increased till it is on the point of flaring. This long, thin flame is a sensitive detector of sound waves, particularly of those of high pitch and tiny amplitude. When a train of these sound waves impinges on the sensitive flame it flares and suddenly shortens. See Fire; Heat.

**Flame Cell**. A specialised cell found in many flat-worms (*Platyhelminthes*). It is hollow and is provided with cilia on the inner surface. Excretory products are collected by the cell, passed into its cavity, and wafted down by the cilia to other drainpipe-shaped cells which, joined end to end, provide a passage to the outside. Its name is derived from the flickering motion of the cilia which, seen under a microscope, somewhat resembles the flickering of a flame.

**Flame-flower** OR RED-HOT POKER (*Kniphofia uvaria*). Perennial herb of the family Liliaceae. It is a native of S. Africa. The leaves, which grow in a compact tuft from the root, are long, narrow, and of tough consistency; they are channelled above and keeled below, the keel and the edges finely toothed. The brilliant

Flame-flower or Red-hot Poker

red, tubular flowers are disposed in a close oval spike, at the summit of a stem 3 ft. or 4 ft. high. The aspect of the flowers gives the herb its descriptive name.

**Flamen.** In ancient Rome, a priest devoted to the service of a particular god. The chief of these priests, who had to

belong to the patrician order, was the flamen Dialis or priest of Jupiter. Not only the flamen Dialis himself, but his wife, who was called Flaminica, and the whole household were regarded as consecrated to the god.

**Flame Weapon.** Reservoir of inflammable oil which can be thrown to a distance in the form of a spray of fire. The oil is forced through a nozzle by means of gas or compressed air contained in a subsidiary reservoir and is ignited by a trigger-controlled device fitted to the end of the nozzle. Flame has been utilised as a weapon of war from ancient times. The Greeks had their Greek Fire, and as early as 250 B.C. the Romans devised containers of chemicals which were catapulted amongst enemy troops and ignited into flame upon contact with the ground. A common form of defence was to instal containers of chemicals in front of static military positions and ignite them in the path of advancing troops.

With the development of firearms, flame weapons gradually fell into disuse. They were revived in the First Great War when the Germans introduced the *Flammenwerfer*, a type of blow-lamp originally intended for cutting paths through barbed wire by melting the strands. During the attack on Hooze in 1916 the weapon was used against infantry, and subsequently it was used in trench fighting. Similar flame-throwing equipment was later adopted by the Allied armies. The largest type of flame-thrower held nearly 350 pints of oil, and the smallest 16 pints. A special device was installed on one of the British ships in the raid on Zeebrugge.

Germany continued the development of flame-throwers and

used them in large numbers when she invaded Poland in 1939 and France in 1940. She introduced the tank flame-thrower, pressure from the engine giving the jet, which had a temperature of 2,000° C. and a range of 100 yds. Italy had flame-throwers mounted on Ansaldo tankettes. Russia installed them in the modified 6-ton tank which she used against the Mannerheim line in the Russo-Finnish campaign of 1939-40.

The British army had no flame-throwers in France in 1940, but shortly after the evacuation of the army from Dunkirk there was formed a petroleum warfare department to develop the application of these weapons, chiefly as a

flame traps; these consisted of perforated pipes laid down each side of a coastal gap and fed from underground reservoirs so that burning oil could be sprayed over the whole area.

A development of the old-time fougasse, or mine, which discharged oil instead of metal, and a hedgehog fougasse which could be hidden behind a wall or rise in the ground and electrically fired to jump over it and burst into flame, were used in conjunction with the anti-tank traps dug throughout Great Britain. When erected vertically, these weapons projected a flame 200 ft. into the air, and when laid along the ground shot blazing oil to 150 ft.

at a temperature of 1,500° C. For the defence of aerodromes, a flame-throwing armoured car was developed; it projected flame vertically or along the ground. The Germans took such a serious view of these weapons that many troops training to take part in the invasion were equipped with asbestos suits.

In 1942 the petroleum warfare department began experimenting in the design of mobile flame-weapons for the eventual Allied invasion of the Continent. No hint of possession of these weapons was allowed to escape until D-day, when they burned and blasted their way through the defence. The heaviest of them was the Crocodile. The nozzle and controls were mounted in a

Uffizi Gallery, Florence

defensive measure against the threatened German invasion. A "sea flame barrier" was set up at vulnerable points on the S. coast by piping oil out to sea beyond the low tide mark to form surface pools that could be fired by passing through the pipes a chemical which ignited on contact with sea water. Gaps on rocky parts of the coast were protected by deile

fare department began experimenting in the design of mobile flame-weapons for the eventual Allied invasion of the Continent. Flame Weapon. Wasp flame-throwers attacking in line abreast, risking the danger from one another's flame jets

Churchill tank, and the fuel was carried in an armoured trailer and transferred to the tank at a pressure of 300 lb. per sq. in. through an armoured pipe incorporated with the towing link. The link made it possible for the trailer to be towed over any ground that the tank would travel over. The jet had a range of nearly 200 yds.

For close infantry support, the Wasp was evolved. With a range of 150 yds., it was fitted to a standard Bren carrier, the fuel and compressed gas tanks being also carried thereon. Projectors and tanks were easily removable, should it be necessary for the carrier to resume its normal rôle. The Lifebuoy flame-thrower was an infantry weapon, carried into action on a man's back. It had a ring-shaped container for the fuel and a spherical container for the compressed gas. The flame was projected from a hand-gun which incorporated an igniting mechanism. The Lifebuoy had a range of 50 yds. and was frequently used by parachute troops. These three British flame-throwers could fire round corners, as the fuel ricocheted

and produced fierce fires in nooks and corners of pill-boxes and trenches. Apart from their capacity for physical devastation, they had a powerful psychological effect. See also Incendiary Weapons.

**Flamingo** (*Phoenicopterus*). Order of large birds, nearly related to the ducks. They have extremely long legs and necks, rosy or scarlet plumage with black on the wings, and beaks sharply bent down at an angle. Adult specimens sometimes exceed 6 ft. in height. One European species, four or five American, and one African are known.

Flamingoes are wading birds, as their long legs and necks suggest, and are found in great flocks by the margin of lakes and rivers, feeding on molluscs and aquatic vegetation. When feeding, the flamingo's head is turned upside down and the curved beak acts as a scoop for picking up food. The birds are fairly strong in flight, and can swim well. The nests are made of mud, and when built on land rather resemble large soup plates. When constructed in the water, they are tall and conical. The European flamingo is common in the S. of France and in Spain during the nesting season, and it ranges through many parts of Africa. It is rarely seen in Great Britain. The name is from Span. *flamenco*, derived from Lat. *flamma*, flame, in reference to the bird's colour.

**Flaming Onions.** Incendiary shells used primarily with a view to setting aircraft on fire. The incandescent projectiles are strung together and resemble a string of glowing onions.

**Flaminian Way** (*Via Flaminia*). Ancient Roman road. It took its name from G. Flaminius, censor in 220 B.C., who extended it to Ariminum, making it the first Roman road to cross Italy. Previously it had existed only as far as Spolegium. It issued from Rome at the Porta Flaminia, being a continuation of the Via Latina, and, crossing the Tiber by the Milvian bridge, reached Spolegium by way of Narnia.

**Flamininus, TITUS QUINCTIUS** (d. c. 175 B.C.). Roman general. Before he was 30, he attained the consulship, and in 197 B.C. defeated the Macedonians at Cynoscephalae (q.v.). A clever diplomatist and an

Flamingo. Adult specimens of the European flamingo

admirer of the Greeks and their culture, he was appointed to settle the affairs of that country. At the Isthmian games in 196 he proclaimed amidst great enthusiasm the independence of Greece, really the exchange of a Roman for a Macedonian master. After crushing the Spartan tyrant Nabis, he was honoured by a splendid triumph on his return to Rome in 194. In 192 he was again in Greece and prevented the pro-Syrian party from assisting Antiochus in his struggle against Rome. In 183 Flamininus was sent to demand the surrender of Hannibal from Prusias, king of Bithynia.

**Flamininus, GAIUS** (d. 217 B.C.). Roman statesman. He introduced an agrarian law in 232, providing for the distribution of recently conquered territory in Picenum and Senonian Gaul among the plebeians. During his censorship

Flame Weapon. [Troops equipped with Lifebuoy flame-throwers attacking the enemy concealed behind a hedge

in 220 he built the great Circus Flaminius and extended the Flaminian Way (*q.v.*). He was one of the generals in command of the Roman army at the battle of the Trasimene lake in 217, in which he was slain.

**Flammarion, CAMILLE** (1842-1925). French astronomer. Born Feb. 25, 1842, at Montigny-le-Roi,

*Flammarion*

he studied theology at Langres and Paris. In 1858 he entered the Paris observatory, and was a member of the Bureau des Longitudes in 1862. From 1863 he edited *Cosmos* and *L'Astronomie*. He carried out numerous observations, especially on Mars, at his private observatory at Juvisy. He won wide fame as a popular writer on astronomy, and founded the astronomical society of France in 1887. Among his books translated into English are: *Popular Astronomy*; *Astronomy for Amateurs*. He died June 4, 1925.

**Flammenwerfer**. The German name for a type of flame-thrower first used at Hooze in 1916. *See* Flame Weapon.

**Flamsteed, JOHN** (1646-1719). An English astronomer. Born at Denby, Derbyshire, Aug. 19, 1646, he was educated at Cambridge. From 1684 he held the benefice of Burstow, Surrey. Devoting himself early to the study of astronomy, he was appointed king's astronomer in 1675, with an annual salary of £100, and installed eventually at the new Greenwich observatory, begun in that year. His observations there gave Newton much help in the perfecting of his lunar theory, though there was much ill-feeling between the two men. Flamsteed's chief work was the great catalogue of the fixed stars, the origin of all later catalogues, which was incomplete at his death on Dec. 31, 1719, but was published with his other observations in 1725. This work was edited by F. Baily, 1835.

**Flanagan and Allen**. British music-hall comedians. Robert Winthrop (who adopted the name of Bud Flanagan), born Oct. 14,

1896, and (William Ernest) Chesney Allen, born April 5, 1894, first appeared together in a revue entitled *Us* in 1926. They evolved a type of verbal humour which found full scope in the *Crazy Gang*—an entertainment first given in 1931. Allen retired from the act in 1946. They also wrote and sang sentimental songs, of which *Underneath the Arches* was typical.

**Flanches** OR **FLANQUES**. In heraldry, the dexter and sinister sides of a shield cut off by curved lines, giving the middle an hour-glass form. They are usually borne in pairs, and are classed among the sub-ordinaries (*q.v.*).

Flanches, in heraldry

**Flanders.** That part of the Low Countries which is bounded roughly by the lower reaches of the river Schelde, the Lys valley, and the coast from Calais to the Schelde estuary. The political frontiers of Flanders have varied considerably, but most of this territory now lies in Belgium, and the old name is retained in the two provinces of W. Flanders (*Flandre Occidentale*), and E. Flanders (*Flandre Orientale*). The Flemish provs. are markedly different in character from the Walloon provs. of Belgium, being mainly peopled by peasant Flemish stock, most of whom speak Flemish, a Teutonic language closely akin to Dutch. Ethnologically, a large part of the French dept. of Nord is Flemish, and is often referred to as French Flanders; while that part of the Netherlands between the Schelde estuary and the frontier with Belgium is known as Zeeland Flanders. The chief towns of W. Flanders are Bruges, Courtrai, Ostend, Roulers, Mouscron, Thielt, Furnes, Ypres, Dixmude; of E. Flanders, Ghent, Alost, Audenarde, Eecloo, St. Nicolas, Termonde. W. Flanders, area, 1,248 sq. m.; pop. est. 978,645. E. Flanders, area, 1,147 sq. m.; pop. est. 1,208,265.

The original inhabitants of Flanders were known to the Romans as the Menapii and the Morini, whom they conquered about 51 B.C. During the 7th century Christianity was introduced, chiefly by S. Bertinus, S. Omer, and S. Bavon. The treaty of Verdun, 843, by which the empire of Charlemagne was partitioned among his sons, gave the greater part of Flanders to Charles the Bald of the W. Franks. Finding this part of

his dominion constantly harassed by the Northmen or Normans, he entrusted its defence to Baldwin Bras-de-Fer (Iron-Arm), who founded the historic line of the counts of Flanders. The last of the direct line, Baldwin VII, died in 1119, and Flanders passed to his cousin Charles, called the Good.

In 1157 Count Thierry resigned in favour of his son Philip, who ruled with marked success, being largely responsible for the early economic prosperity of the great Flemish market towns of Bruges, Ypres, Ghent, etc., and who died crusading at Acre, 1191. He left his Flemish dominions to his sister Margaret of Hainault, who thus united the crowns of Flanders and Hainault, though ceding Artois to Philip Augustus of France. Her son, Baldwin IX (1171-1205), emperor of Byzantium, succeeded her in 1194. His daughter, Joanna, was married to Ferdinand of Portugal, who resisted the suzerainty of France, but was disastrously defeated by Philip Augustus at Bouvines, 1214.

After Joanna's death, 1244, the kingdoms of Flanders and Hainault were torn by a war of succession, and were eventually separated by the arbitration of S. Louis, who awarded Flanders to William of Dampierre, and Hainault to his stepson, John of Avesnes, 1246. Guy of Dampierre, who succeeded in 1280, waged war, in alliance with Edward I of England, against Philip the Fair of France. Supported by popular feeling, directed by the Flemish patriots, Deconinck and Breydel, he routed the strong force of French knights near Courtrai, 1302, and for a time Flanders was definitely free from France. But under Louis of Nevers, 1322-46, it was again virtually a French fief.

#### Resistance to French Rule

The following period of internal dissensions was marked chiefly by the resistance of the Flemish communities to the arbitrary and extortionate rule of Louis II of Mâle, who succeeded in 1346. John and Philip van Artevelde (*q.v.*) hold a great place in Flemish history as spokesmen and leaders of the popular party, or White Hoods. By the autumn of 1382 Philip had become very powerful in W. Flanders, established in Bruges, and assured of the people's support. But at Roosebeke, Nov. 27, 1382, he was utterly defeated by Louis with the aid of Charles VI of France. Thenceforth Louis ruled with a firm hand until his death, 1385, when Flanders fell to

*John Flamsteed*

his daughter Margaret, wife of Philip the Bold of Burgundy.

From this date Flanders was for historical purposes part of Burgundy, until, in 1477, Mary of Burgundy married the emperor Maximilian and brought it into the empire. It was in this period that the extraordinary economic prosperity of the great Flemish towns reached its highest point. The abdication of Charles V brought Flanders into the Spanish dominions under Philip II in 1555, introducing the long wars for the independence of the Netherlands, and the old-time prosperity suffered sadly. In 1648 the treaty of Westphalia made Flanders part of the United Netherlands, and in 1659 and 1713 Louis XIV absorbed large parts of Flemish territory as well as Artois. In 1714 the treaty of Rastatt put Flanders again into Austrian possession, and in 1794 it fell into French hands once more. But when the new kingdom of Belgium was formed in 1830, Flanders entered into her present position therein.

Neither these many changes of sovereignty, nor the unfortunate position of Flanders as a battlefield of the nations, has destroyed the individual character of the Flemings or their country. Within Belgium itself racial consciousness is sharply marked. The possession of a tongue and literature of their own has given the Flemish national movement considerable strength. It has won recognition of Flemish rights, linguistic and educational, and is an important factor in Belgian politics. A strong body of feeling has long favoured Flemish autonomy.

**Flanders, BATTLE OF.** Name given to one of the final battles of the W. front in the First Great War which brought about the military defeat of Germany by the Allies. It was fought Sept. 28–Nov. 11, 1918. The heavy fighting in Flanders in 1914, sometimes called the 1st battle of Flanders, is more generally known under the titles Ypres and Yser. In the Second Great War, the Allied campaign in Flanders of May, 1940, which ended in the retreat upon Dunkirk, was also described as the battle of Flanders in the title of a popular semi-official account published the following year, but is dealt with in this work under British Expeditionary Force.

In 1918, in accordance with the general plan of Foch, the Allied c.-in.-c., a group of Belgian, British, and French armies was

placed under command of the king of the Belgians, and opened an attack on a front extending from Dixmude to the S. of the Ypres salient on the morning of Sept. 28. In spite of heavy rain, by Oct. 1 all the German main defensive line on the Flanders front was penetrated to a depth of over 8 m. The Germans at once began preparations for the evacuation of the Flanders coast, which they had at one time decided to annex permanently.

After a pause for reorganization the Allies resumed the attack on Oct. 14; and a slow German retreat along the whole front continued up to the date of the armistice, Nov. 11. The Allied troops had to march and fight with German rearguards in difficult country with bad communications. Mines with delay-action fuses were left by the Germans at every cross-roads and at many points on the railways, and these exploded sometimes weeks after their retirement. In the first phase of the battle some 10,000 German prisoners were taken; in the second phase, some 18,000.

**Flanders Poppy.** Artificial flower sold on Remembrance Day, originally Nov. 11 (sometimes called Poppy Day) to support Earl Haig's appeal fund for disabled ex-Servicemen. The scarlet wild poppy grows in such profusion in Flanders that it was chosen as the commemorative emblem of this fund, which was founded to aid ex-servicemen of the First Great War. See Armistice Day.

**Flandin, EUGÈNE NAPOLEON** (1809–76). French painter. Born in Naples, Aug. 15, 1809, he studied in Italy, and under Horace Vernet in Paris, and travelled widely in the East. He painted many landscapes, notably of Venice, Athens, Algiers, and Constantinople, and wrote valuable accounts of his travels and archaeological discoveries. He was awarded the Legion of Honour in 1842, and died Feb. 15, 1876.

**Flandin, PIERRE ÉTIENNE** (b. 1889). French politician. He was born in Paris, April 12, 1889, educated at its university, and entered the legal profession. In 1914 he was elected deputy for Yonne, and later held many cabinet appointments, being prime minister in 1934–35 and foreign minister in 1936. Of the moderate Right and with industrial and financial connexions, he worked for a rapprochement between France and Germany and was in favour of terminating the alliance with Great

Britain. After the capitulation of France in June, 1940, Flandin retired to the German-occupied

P. E. Flandin,  
French politician

area, but in Dec. was appointed foreign minister in the Vichy government. He resigned Feb. 9, 1941. Arrested in Algeria, Oct. 8, 1944, he was interned in Fresnes prison, near Paris, and on March 1, 1945, the high court ordered the sequestration of all his property. In 1946, Flandin was found guilty of "national indignity" by participating in the Vichy government and was sentenced to five years' loss of civic rights; but was at once exonerated in view of his past services to the resistance movement.

**Flandrin, JEAN HIPPOLYTE** (1809–64). French painter. Born at Lyons, March 23, 1809, son of a miniature painter, he studied there and at Paris under Ingres (*q.v.*). Obtaining the Grand Prix in 1832, he went to Rome, whence he returned in 1838 to Paris, and was employed in the mural decoration of S. Séverin, 1841, S. Vincent-de-Paul, 1850, and other churches at Paris and elsewhere. Later he took to portrait-painting, among his best works in this genre being the full-length portrait of Napoleon III, at Versailles. He died of smallpox at Rome, March 21, 1864.

**Flandrin, JEAN PAUL** (1811–1902). French painter. A brother of J. H. Flandrin, he was born at Lyons, May 8, 1811, and studied under Ingres. He was a prolific artist, his best work being of landscapes. Among the most noteworthy are *Solitude in the Sabine Mountains*, 1852, in the Luxembourg, Paris; *The Rhône*, 1857; *Meadow near Mantua*, 1874; and *Diggers at Work*, 1884. He was awarded the Legion of Honour in 1856, and died March 10, 1902.

**Flange.** A projection which guides, strengthens, or affords a means of attachment. Flanges are used for a number of purposes, the designs taking many forms. To prevent lateral movement of a belt or rope the wheels over which it runs are often provided with circumferential flanges. A similar method is adopted for wheels running on rails, with the important difference that it is the travelling member which is flanged. Flanges may also be suitably positioned, to

give additional strength to steel beams and girders. A further purpose is that of joining two individual members of a structure, e.g. water and gas pipes. In railway wheels the flanges are forged to shape, but for the production of girders or beams they are formed by hot rolling between rolls. Casting is a third method used in the production of the component itself, e.g. flanges on cast iron pipes.

**Flank.** Military term used for the side of a unit, whether in column, line, mass, or any other formation. On the march troops are protected by flank guards, and when taking up a position by outposts, unless the nature of the ground makes an attack impossible. See Tactics.

**Flannan Isles.** Cluster of seven small islands in the Outer Hebrides, Ross and Cromarty, Scotland. Called also the Seven Hunters, they lie 16 m. W.N.W. of Gallon Head, Lewis Island, and contain many Caledonian remains. They are the *Insulae Sacrae* of Buchanan. Large numbers of sea-fowl frequent them. Flannan Isle is the title of a poem on the supernatural by Wilfrid Gibson.

**Flannel.** Soft woollen cloth used for clothing, blankets, etc. Highly absorbent, it is eminently adapted for wearing next the skin. The word is probably of Celtic origin (*cf.* Welsh *gwlan*, wool). Wales is the original home of the flannel industry, and has long held flannel fairs. Falstaff calls Sir Hugh Evans the "Welsh flannel." Welshpool, Montgomeryshire, formerly the chief seat of the manufacture, has been superseded by Newtown. Lancashire and Yorkshire are noted for flannels, particularly Rochdale. See Blanket.

**Flannelette.** Cotton imitation of flannel, used for pyjamas, underwear, etc. The term was first used towards the end of the 19th century. Flannelette has lost much of its former popularity as it lacks the absorbent properties of flannel, and is liable to catch fire.

**Flap.** Device fitted to aircraft wings to enable high-speed machines to land on constricted aerodromes. Flaps are fixed to the trailing edge of the wing and are hinged to move downwards. When down they offer resistance to the air and so act as a brake upon forward movement. In normal flight the flaps are kept in the same plane as the wing surface and are controlled by a lever in the cockpit. Dive-bombers are fitted with large flaps to check downward momentum during the dive (*see* Dive

Flap fitted to aircraft wing

Brake). By a combination of flaps and slots, the slots being fitted to the leading edge of the wing, a high-speed aircraft can be flown safely at remarkably low speeds. The slots smooth out the airflow over the upper surface of the wings, while the flaps give an increase in lift.

**Flare.** Fireworks of the nature of coloured fires. They were used during the Great Wars and in later operations, e.g. in Greece, to illuminate portions of the front at night, and sometimes arranged so that they were automatically ignited if anyone moving about stumbled over a trip wire placed in front of the position. Screens were arranged behind the flares so that the enemy troops were illuminated, while their opponents remained in the shadow and were not inconvenienced by the light. Small hand flares of the Very light (*q.v.*) type were used for both illumination and signalling, and generally burned for about three minutes. Larger ones were thrown from trench howitzers. During the Second Great War flares were dropped from aircraft by parachute to illuminate targets during bombing attacks. Flares intended to illuminate the ground usually contained a mixture of powdered magnesium and a chlorate or nitrate of one of the alkali metals. They gave an intense white light, throwing strong shadows. Life-buoys usually have attached to them a canister of chemicals which automatically ignite on contact with water and emit a bright yellow flare. Signal flares of various colour are obtained from such constituents as the following, combined in the proportions shown.

	Red	Green	Blue	Yellow
Potassium chlorate ..	78	—	45	—
Strontium carbonate ..	15	—	—	—
Shellac ..	7	1	5	—
Barium chlorate ..	—	66	—	—
Milk sugar ..	—	33	—	—
Sodium nitrate ..	—	—	—	70
Sulphur ..	—	—	—	20
Antimony sulphide ..	—	—	—	7
Lampblack ..	—	—	5	3
Basic copper carbonate ..	—	—	10	—
Calomel ..	—	—	85	—

**Flare Path.** Lights set along the edge of a runway or laid out to form a path on an airfield to enable aircraft to land at night. On permanent runways the lights are set flush in the ground on either side of the tarmac and lit electrically. On temporary airfields the flare path is lit by portable oil lamps. It is always lit or laid out so that the pilot comes in to land into the wind, coloured lights giving him his direction.

**Flash.** Piece of broad black silk ribbon with long ends, which is attached to the back of the tunic

Flash. Distinctive emblem worn by the Royal Welsh Fusiliers

collar of the Royal Welsh Fusiliers. This is a relic of the days when soldiers wore their hair powdered and tied in a queue; the flash served to keep grease from soiling the back of the tunic. During

both Great Wars the term flash was applied to the strips of printed or embroidered or coloured material worn on the shoulders of army tunics or blouses to denote regiments and formations. Dominion servicemen and Allied subjects serving with the British services in the Second Great War wore shoulder flashes indicating their dominion or nationality. Flashes worn by civil defence personnel denoted their particular functions.

The term is also used for the tasselled end of the strip of material used as a garter in Highland dress.

**Flash Bomb.** Missile to assist air-to-ground photography, developed during the Second Great War. The R.A.F. used 1,000,000 candle-power cartridges for low altitude photography purposes and 200,000,000 c.p. flash bombs for greater heights. Night photography by the U.S.A.A.F. was carried out at still greater heights with 700,000,000 c.p. flash bombs, a large area being photographed with a single exposure lasting about  $\frac{1}{10}$  sec.

**Flashlight Photography.** Photography by the brilliant light obtained by burning magnesium. It is used chiefly for portraits, groups, and interiors of moderate size. In one apparatus fine magnesium is blown through the flame of a spirit lamp, but the magnesium is usually combined with chlorate or perchlorate of potash, and fires readily on the application of a taper or electric spark. The

chief drawback to these "flash-powders" is the smoke which is produced by them. To overcome this defect, photo-flashes or flash bulbs have been produced consisting of a bulb containing magnesium foil in an atmosphere of oxygen and other gases. An instantaneous flash is produced by the rapid combustion of the magnesium foil, giving an intense white light of 25,000-55,000 lumen-seconds. The flash is initiated by a small filament heated momentarily by an ordinary dry cell. Flash bulbs, which can be used only once, are arranged to screw into a pocket torch.

**Flash Point.** Temperature at which a substance gives off sufficient vapour to form an inflammable mixture with air. The test is specially applied to petroleum products and is indicative of volatility and fire hazard. The substance under test is contained in a metal cup which is evenly heated at a stated rate. A small test flame is applied at regular intervals to the vapour space in the cup until a bluish flame appears; the temperature of the substance at that instant being recorded as the flash point. Heating may be continued until such time as the vapour burns continuously for at least 5 secs.; the temperature of the substance then is recorded as the fire point. A lower figure will be obtained if the cup is fitted with a cover than if it is open.

Standardisation of apparatus and procedure is essential. In Great Britain the Abel tester is specified for substances with flash points below 120° F. and the Pensky-Martin apparatus for substances flashing above that temperature. A minimum flash point

(Abel, closed cup) of 73° F. is demanded for kerosene by the British Petroleum Act. The minimum for fuel oils is usually 150° F. (Pensky-Martin, closed cup). This minimum is specified so that an inflammable liquid is safe in its normal conditions of storage and use. Recognition of the nature of the liquid is as important in avoiding the danger of explosion and fire as is compliance with statutory standards.

**Flash Spectrum.** Transient spectrum of the sun's atmosphere, first observed at the total eclipse of 1870. As the moon moves across the narrowing crescent of the sun's disk, the absorption spectrum of the solar surface gives way to a bright-line spectrum which flashes out for a few seconds until the sun's atmosphere, too, is covered by the moon. The reverse phenomenon happens a few minutes later when the moon uncovers first the sun's atmosphere and then the bright disk itself. Study of the flash spectrum enables the physical condition as well as the chemical composition of the sun's outer layers to be deduced.

**Flask.** (1) In founding, a wooden or iron box or frame-like structure for holding the sand or material forming a mould into which molten metal is poured for making a casting in a foundry. The flask comprises a cope, or top member; a drag, or bottom member; and, when used, intermediate members termed cheeks. If the mould is contained in two or more members, the structure is known as a two-part flask, a three-part flask, etc.

(2) Vessel of glass, metal, etc., usually having a neck, and provided with a body portion which

may assume a variety of shapes, for use in storing and heating liquids, and, formerly, as a receptacle for gunpowder.

(3) In ordnance, a metal reservoir for storing compressed air which forms the actuating medium of a motor for an automobile torpedo.

**Flat.** Separate residence, one of several, each at one level, in a single building. Where the planning arrangements are similar but the accommodation of each dwelling is on more than one floor, the dwellings are called maisonnettes. Blocks of flats or maisonnettes fall into two main classes: (1) those provided by local authorities, voluntary planning associations, or housing trusts, the rents being artificially reduced by subsidy; (2) commercial flats built and let on a profit-making basis.

Living in flats has now become an accepted feature of British social structure, for ownership of a house with its own garden is often precluded by the need to live near the centre of a large town. In areas populated by, say, 150 persons per acre, housing is normally possible only in flats. The siting of blocks is important. There must be ample space between them to avoid overshadowing, and to provide sufficient sunlight, fresh air, and open space. Blocks running N.-S., with windows facing E. and W., provide the best arrangement. Ideally bedrooms and kitchens should be on the E. and living rooms on the W.

The balcony access type is probably the most economical in cost, particularly where lifts are installed, access to each flat being from a long external balcony at each floor. In the direct access type, each flat is entered directly from the staircase, which may serve two or more flats at each floor. This gives a greater degree

of privacy, better ventilation, and more sunlight. The corridor access type, in which the flats are approached from each side of an internal corridor, is more suited to hotel planning than to flats, built commercially with

profits a first consideration, because mechanical ventilation, with increased capital and maintenance costs, is generally necessary for the corridors.

Flat. Architect's lay-out of the first floor plan of a three-storey block of flats, showing the advantages of the balcony access type; each of the adjacent flats is entered through a private balcony from a common staircase

The limit of heights of individual blocks is controlled by legal limitations and by the cost of construction. Hitherto the majority of blocks provided by local authorities have been of five storeys, the lowest three floors being planned as flats and the upper two as maisonnettes. Cost increases disproportionately above eight or nine storeys, but buildings six or seven storeys high are likely to be common. Lifts may be provided in blocks of more than three storeys built by local authorities under the terms of the Housing Act, 1946. Sites on main roads often have shops on the ground floor. Gardens, children's playgrounds, and accommodation for communal activities are desirable features of large estates.

Social changes have rendered obsolete many large houses originally intended for single families, but many of sound construction have been converted into flats. Large detached or semi-detached houses are usually comparatively easy to deal with. For terrace houses it is better to convert a number together, uniting the buildings at each floor level by breaking through the party walls. Redundant staircases can then be removed.

**Flat.** In music, a sign ( $\flat$ ). It indicates that the note to which it refers is to be a semitone lower in pitch than the ordinary note of the same alphabetical name or in the same position on the staff. It was first applied to the note B, and the sign was actually a little b, to distinguish this note from  $\sharp$  B, which in Germany was and is still called H ( $\sharp = h$ ). See Double Flat; Natural; Semitone; Sharp.

**Flatbush.** District of Brooklyn, U.S.A., one of the boroughs of King's co., Long Island, it became part of the borough in 1898. It was settled by the Dutch in 1651. On Aug. 23, 1776, Lord Cornwallis's division of Lord Howe's army occupied Flatbush, and the battle of Long Island fought four days later is sometimes called by this name.

**Flateyjarbok.** Icelandic manuscript dating from the 14th century. Among other things it contains some account of the voyages of the Norsemen of the 10th and 11th centuries to the American continent. Flateyjarbok (the Book of Flatey) is preserved at Copenhagen. Consult Anecdotes of Olave the Black, J. Johnstone, 1780; Flateyjarbok, ed. G. Vigfusson and C. R. Unger, 1860-68.

**Flatfish** (*Pleuronectidae*). Large group of fishes of flattened shape, in which the two sides are unlike in colour and the two eyes are on one side. The plaice and sole are examples. In these fish the body is greatly compressed laterally. In early life the flatfish are symmetrical, and swim like round fishes. Then they become flattened, the body tilts over, and the fish takes to swimming on its side and to lying on the bottom of the sea. The upper side then becomes darkened, and assumes a hue which approximates to the nature of the ocean bed on which it lies, while the markings closely resemble the gravel and mottings of the sand or mud. At the same time, the eye on the under side gradually works round to the upper surface and the mouth becomes more or less twisted. The eyes stand out from the head and

can be turned independently in different directions. Flatfish are marine in habit, though flounders frequently ascend rivers, and a few species have adapted themselves to a life in fresh water. Most are good table fish.

**Flat Foot.** In mankind, a condition in which the arch of the foot is reduced, or in bad cases nearly abolished, so that almost the whole extent of the sole comes in contact with the ground. Flat foot is most common in young persons of poor physique, whose occupation has necessitated their standing for long periods, or frequently carrying heavy weights. Occasionally it may result from injuries which have torn or weakened some of the ligaments of the foot.

Flat foot produces feelings of fatigue and weakness after a comparatively small amount of exercise. Irritability and headache result from jarring of the brain pan, the transmission of which jarring through the spinal column is prevented by the spring of the normal arch. Severe pain may be felt in the sole, and the gait becomes shuffling and awkward. Eventually the whole posture of the body may be altered, particularly when the condition is more marked in one foot than in the other. Compensatory changes may result in a tilting of the pelvis, curvature of the spine, and even changes in the position of the shoulders.

In early cases, where weakness rather than actual deformity of the arch is present, rest should be enjoined; at the same time the patient should undergo a course of instruction in exercises specially designed to strengthen the weak parts. Electrical stimulation of the muscles helps. When the condition is more marked it is necessary to afford artificial support to the arch of the foot by instep-pads worn inside the shoes,

Flat Foot. Illustration of a severe case. Upper diagram shows the foot with corrective apparatus supporting the arch

or by raising the inner part of the shoe sole. These measures, however, merely relieve the symptoms, and have no curative power. In chronic cases, remedial measures may prove useless, though a surgical operation may relieve the condition. *See Foot.*

**Flatford.** Village of Suffolk, England, on the Stour near the Essex border. Its fame rests on its mill, which formed the subject of a picture by John Constable. The mill-house, restored, was presented to the National Trust in 1928 and in 1946 was leased by the Council for the Promotion of Field Studies.

**Flatman,** THOMAS (1637-88). English miniaturist. He was born in London, and educated at Winchester and New

College, Oxford, of which he was scholar and fellow. He became a barrister and practised poetry and miniature painting as an amateur, the latter with conspicuous success. Walpole cites a portrait of Dr. Tooke's father by him which was highly praised by contemporary connoisseurs. He died Dec. 8, 1688.

**Flattery.** Cape or promontory of Washington, U.S.A. At the S. side of the entrance to the strait of Juan de Fuca, it is the extreme N.W. point of the state. There is another cape of this name in Queensland, Australia, in Banks co. about lat. 14° 52' S.

**Flatulence** (late Lat. *flatulentus*, full of wind). Term describing an undue amount of gas in the stomach or intestines. In the normal digestive tract anything over the normal amount of gaseous product is absorbed by the lining mucous membrane; flatulence can be caused by hysteria, a wrong balance of acid and alkali, inadequate secretion of bile, or mechanical blockage causing a reflex hold-up of the intestinal contents. Much flatulence travelling in an upward direction nearly always implies air-swallowing; many hysterical women habitually swallow air. Gas may occur from fermentation in the lower part of the digestive tract when the bile is unable to discharge its anti-bacterial function. The food-stream may be too acid or too alkaline. A duode-

nal ulcer, an inflamed appendix, a haemorrhoid, or any new growth of the intestinal tract may give rise to this condition.

Relief is obtained by removing any mechanical cause and adjusting food intake and the rate and time of intake so as to correct any chemical imbalance. The importance of adequate biting surface for the teeth cannot be overstressed.

Flatford, Suffolk. Mill on the river Stour, subject of a famous painting by Constable, and now the property of the National Trust

**Flaubert, GUSTAVE** (1821-80). French novelist. Born at Rouen, Dec. 12, 1821, the son of a surgeon, he went to Paris to study law in 1840, but spent a number of years in travel, visiting the East in 1849-50. Returning to France in 1850, he settled at Croisset, near Rouen, and began his first novel,

*Madame Bovary*. It took six years of constant labour and was published serially in 1857. An action against author and publisher for its alleged immorality was dismissed, and the book, his undoubted

masterpiece, made his name famous. There followed an epic story of Carthage, *Salammbô* (Eng. trans. M. F. Sheldon), 1862; *L'Éducation Sentimentale*, a survey of contemporary life, 1869; *La Tentation de S. Antoine* (Eng. trans. R. Francis), 1874; *Trois Contes*, 1877; and the posthumous *Bouvard et Pécuchet*, 1881. Flaubert died May 8, 1880, having long been broken in health.

He was the dominant figure among French novelists of the last epoch of Romanticism. A literary

descendant of Balzac, he was by turns a sheer realist and a sheer romanticist, in both aspects brilliant and infinitely laborious. He took his art very seriously, tormenting himself for days in the search for a word, polishing his work with untiring zeal. His technical skill, especially as a realist, greatly influenced later French writers, in particular the de Goncourts and Zola. An edition of his works in 18 vols. was completed in 1910. There are Lives by E. Faguet, 1899; J. Wassermann, 1906; L. Bertrand, 1912. *Pron.* Flo-bare.

**Flaveria contrayerba.** Biennial herb of the family Compositae. A native of Peru, it has opposite, saw-toothed, lance-shaped leaves, and yellow flower-heads. In Chile a yellow dye is obtained from them.

**Flavine** (Lat. *flavus*, yellow). Complex organic substance used as an antiseptic. Its value was discovered in 1916 by the Bland-Sutton institute for clinical pathology at the Middlesex Hospital, London. The discovery of the drug itself was due to Prof. Ehrlich, who treated cases of sleeping sickness with it. Flavine is a yellow dye belonging to the acridine series, hence its official name acriflavine. It is harmless to the tissues, though it may sometimes form scars. The discovery of its efficacy as an antiseptic was hastened by the need for such a drug occasioned by the First Great War. *See* Antiseptics.

**Flax** (*Linum usitatissimum*). Annual plant of the family Linaceae. Its native country has not been decided with certainty; there appear to be at least two centres of origin, S.W. Asia, to which a small flower and small seed form are peculiar, and the countries on the S. shores of the Mediterranean, where a large flower and large seed form predominate. The form known in the British Isles

Flax. Stem, leaves, and flowers of *Linum usitatissimum*

and other countries where flax is grown for its fibre is a fine unbranched erect plant, 3-3½ ft. high, with small alternate lanceolate leaves and usually blue flowers; the fruit is a spherical capsule with five compartments each containing two brown, lens-shaped seeds. Although the flowers are usually blue, with blue or yellow pollen grains, there are fibre varieties with white flowers and either blue or yellow pollen grains.

When intended for high quality fibre, the plant is pulled by up by hand or by mechanical means, and tied in small bundles preparatory to "retting." The crop is pulled before the seed is ripe; consequently the crop cannot have a dual purpose, the producer deciding upon either seed or fibre. Retting, or literally rotting, consists of submerging the sheaves of flax in ponds or slowly flowing streams for 8-12 days, during which a process of fermentation is set up that separates the outside and inside layers of tissues of the stem from the phloem or fibrous portion. After retting the sheaves are opened and the flax is spread out to dry; after drying, it is subjected to scutching, a mechanical means of separating fibre from other portions of the stem. After the removal of all adhering portions of the stem, fibre is transferred to the spinner and then to the weaver, by whom it is converted into the desired textile.

Linen has been used by man since the dawn of history. In

Flaxman. Mercury and Pandora, an example of John Flaxman's work

England in Tudor times, and later, the cultivation of flax was made compulsory. Although flax is still grown to a limited extent in England, British cultivation on a substantial scale is now confined to N. Ireland. During the Second Great War the main sources of supply, notably Belgium, were

cut off, and efforts were again made in England to grow flax for fibre. The yield of scutched flax per acre varies seasonally; the highest recorded in N. Ireland was 48 stones in 1847, and the lowest 12.7 stones in 1871; on an average it is between 25 and 30 stones. Linseed, i.e. seed of the flax plant, is produced for commercial purposes in India and Argentina. Seed rather than fibre being the objective, plants with short straw and strongly developed branching habit and large seed are cultivated. Approximately one-third of the weight of linseed is oil, and the residue of the seed after oil has been abstracted forms a valuable livestock concentrate. All forms of flax require well tilled land, free of weeds, and an ample supply of potash; the fibre crop also succeeds best in localities with ample rainfall and a general high humidity.

**Flaxman, JOHN** (1755-1826). English sculptor. Born at York, July 6, 1755, he was the son of a maker of plaster casts. Owing to physical deformity, his childhood in London was passed mainly in his father's shop, where he drew, modelled, and studied the classics. In 1770 he entered the Academy schools, having previously exhibited and gained awards at the Society of Arts, the Free Society of Artists, etc.; and in 1775 began to be regularly employed by the Wedgwoods in designing classical friezes and medallions for their ware. Married in 1782, Flaxman and his wife went to Rome in 1787. Returning in 1794, they settled in London. In 1797 he was elected A.R.A., and R.A. in 1800, and in 1810 was appointed professor of sculpture. He died Dec. 7, 1826.

Flaxman's most notable monumental works are in Westminster Abbey and St. Paul's, his classical figures and groups at Petworth, Woburn, and other country seats, and his characteristic memorial reliefs are numerous in the British

cathedrals and churches. Collections of his drawings are in the British and South Kensington museums, and the Fitzwilliam museum, Cambridge. University college, in Gower Street, London, housed in the Flaxman gallery original drawings and sketches in pen and pencil, and also plaster casts from his clay models. This collection was badly damaged in German air raids in 1940. See Sculpture.

**Flea** (order Aphaniptera or Siphonaptera). Group of about 1,000

Flea. Much enlarged specimens. 1. Rat flea. 2. Common flea, *Pulex irritans*, male and, 3, female

1 Photographed at Nat Hist Museum, S Kensington

species of small wingless insects, living when adult as parasites on birds or mammals. The body is laterally compressed, with a tough, shiny integument. The hind legs are very large and used for leaping. The vertical leap of the common flea is stated to be 7½ ins. Usually each species lives on a particular host, but many can live, at least temporarily, on a different host. The mouth-parts are piercing organs used for sucking blood—the staple food of fleas. The rat flea migrates readily to man, and is a carrier of the bacillus of bubonic plague. Eggs of fleas are normally laid in the haunts or sleeping places of the hosts. The larvae are worm-like and feed on debris, those of the common flea taking in organic particles among the dirt of floors.

**Fleabane** (*Pulicaria* and *Eriogeron*). Group of herbs of the family Compositae. *P. dysenterica*, a native of Europe, N. Africa, and

Fleabane. Leaves and flowers of *Pulicaria dysenterica*

the Himalayas, is a perennial, with creeping rootstock, erect stems, and heart-shaped, oblong, woolly leaves. The daisy-like flower-heads are bright yellow. It was formerly used as a medicine in dysentery. Canadian fleabane (*Erigeron canadensis*), generally distributed in warm and temperate regions, is an annual, with stem 1 or 2 ft. high and narrow, lance-shaped leaves. The small, yellow-centred, white flower-heads are clustered.

**Flèche, LA.** Town of France. It stands on the Loir, 24 m. S.W. of Le Mans, in the dept. of Sarthe. It is an agricultural centre, trading in corn, wine, etc., and has also some small manufactures; its buildings include a town hall, museum, and theatre. More famous is the military school here known as the Prytanée, from which students pass to St. Cyr. Founded in 1774, this occupies the buildings of a Jesuit College, and has a large library. The earlier college, at which Descartes was educated, was founded in 1604 by Henry IV, to whom there is a statue in the market place. La Flèche was liberated in the rapid U.S. advance at the beginning of Aug., 1944. Pop. 11,293.

**Flecker, JAMES ELROY** (1884-1915). British poet. Son of a clergyman and born in London, Nov. 5, 1884, he was christened Herman, which name he changed to James later. He was educated at Dean Close, Cheltenham, Up-pingham, and Trinity college, Oxford. He joined the consular service in 1910, the year in which his Twenty-Six Poems appeared, and served in Constantinople (Istanbul) and Smyrna (Izmir); but tuberculosis forced him to abandon his profession, and he died at Davos, Jan. 3, 1915.

Flecker early showed signs of becoming one of the most notable poets of his generation, and lived to see his work recognized by the critics. He possessed a fine, lyric quality, and took a sensuous delight in words of colour. Such poems as *The Old Ships*, *The Dying Patriot*, and *To a Poet a Thousand Years Hence*, found a permanent place in anthologies; others include *The Golden Journey to Samarkand*, and *Oak and Olive*. The oriental drama *Hassan* (q.v.) is considered his masterpiece. Flecker's poems were collected by J. C. Squire in 1916 (new ed. 1946), and biographical volumes were published by D. Goldring, 1922, and G. Hodgson, 1925. *Consult* Some Letters from Abroad of J. E. F., 1930.

**Fleece.** Coat of the live sheep removed by shearing and forming a fairly coherent mass by the interlocking of adjacent fibres. Fleeces deprived of some of their inferior portions are rolled into bundles, secured by a twist of their own fibre, and packed into bales or into bags known by the trade name of sheets. Locks and pieces are portions of the coat separated by accident or design from the main bulk or fleece. In the course of wool-sorting the fleece is opened out and examined. Fleeces of like quality placed together are described as cased.

Wool of different strengths grows upon different parts of the body, and in sorting wool fully the fleeces are broken up. When the respective sorts of wool from many fleeces have been collected together the lots are given the name of matchings. The term fleece wool in some parts of the country implies wool not of the first clip. Certain manufactured goods, e.g. warm linings, are called fleece from their warmth and fleecy appearance. *See* Wool.

**Fleet** (A.S. *flēotan*, to float; cf. Ger. *fließen*). Naval term signifying a number of ships under the supreme command of a single officer. In the Royal Navy a battle fleet consists of five or more capital ships with attendant cruisers and destroyers and supply vessels. At one time fleet was synonymous with squadron, but nowadays the fleet is a much larger unit. A group of vessels operating in a specified area is generally given the title of fleet; thus in the Second Great War there was the Pacific Fleet. In peace-time the Royal Navy is divided into the Home, Atlantic, and Mediterranean fleets. In the U.S. navy the word has largely been replaced by the term task force. The whole navy of a nation is often called the fleet, e.g. the British fleet. *See* Fishing Fleet; Grand Fleet; Navy; Squadron.

**Fleet.** Urban district of Hampshire, England. It is 6 m. N.E. of Odiham and 36 m. S.W. of London, with a rly. station. A feature is Fleet Pond, a sheet of water 130 acres in extent. Pop. 8,100. There is also a village of this name in Lincolnshire, 2 m. S.E. of Holbeach, on the rly. Pop. 1,334.

**Fleet, THE.** Name of the navigable part of an old London river which, rising in Hampstead, entered the city S. of Chick Lane (now Charterhouse Street) and joined the Thames at Blackfriars. First mentioned in a 12th century MS., it was known as the Fleet Ditch, owing to the frequency with

which it became choked with refuse. The N. part was known as the Holebourne, whence Holborn. After the Great Fire of 1666 it was cleansed, deepened, and called the New Canal. Wharves were erected as well as bridges at Holborn, Fleet Lane, Fleet Street, and Bridewell. The part between Holborn and Fleet Street was arched over in 1737, and later the stream was converted into a sewer, its course being covered by Farringdon Street (q.v.) and New Bridge Street.

**Fleet Air Arm.** Name of the Royal Air Force component attached to the Royal Navy, 1922-1937. It continued in common use after the formation of the Air branch of the R.N. in 1937.

Flying from ships began in 1911 (*see* Aircraft Carrier). With the amalgamation of the R.N.A.S. and the R.F.C. to form the R.A.F. on April 1, 1918, all aviation came under the Air ministry. This first introduced non-naval personnel into the air component of the R.N. When the R.A.F. was reorganized for peace-time duty in Dec., 1919, R.A.F. units attached to the fleet for naval air duty were administered by a new R.A.F. command called Coastal Area.

The F.A.A. was created in 1922 to give the R.N. a measure of participation in the R.A.F. naval air component. Thereafter, air units allotted to the F.A.A. included a proportion of naval officer pilots, eventually reaching the maximum proportion of 70 p.c. naval to 30 p.c. R.A.F. personnel. Navigator and observer duties were carried out by specially trained naval officers. Naval ratings were trained as wireless-operator/air-gunners. The officer in command of flying and the aircraft engineer officer in each ship were for many years R.A.F. officers. R.A.F. airmen serviced the aircraft and engines and airframes on board ship and ashore; naval ratings provided the aircraft handling parties. Naval pilots (but not the observers) were seconded to the R.A.F. while attached to the F.A.A. and held commissions at equivalent rank in the R.N. and the R.A.F.; but R.A.F. pilots were not seconded to the R.N.

The Admiralty had full operational control over all R.A.F. units allotted to the F.A.A., and full disciplinary control when units were embarked. The Air ministry had administrative and disciplinary control when units were disembarked to shore air stations (which were then ex-

clusively R.A.F.), retained the functions of design and supply of aircraft and equipment (in consultation with the Admiralty), and undertook initial flying training. The first naval officer pilots' course began in 1924. Pilots were normally seconded to the F.A.A. for four years, after which they returned to purely naval duty.

The F.A.A. was organized in squadrons and flights, with squadrons normally posted to aircraft carriers, and flights to fleets or naval squadrons for duty in fighting ships fitted with catapults (battleships, battle cruisers, and cruisers carrying from one to four aircraft). Fighting ship aircraft were usually either seaplanes or amphibians, able to alight in the water alongside to be hoisted inboard after flight. Except for experimental aircraft, carrier-borne aircraft were landplanes fitted with deck arrestor gear.

By March 31, 1931, the strength of the F.A.A. was equal to 13 squadrons (about 156 operational aircraft) to meet the requirements of six aircraft carriers and various fighting ships. In May, 1935, the first-line strength was 175 aircraft. In 1937 the R.A.F. Far East command administered five and the R.A.F. Mediterranean command eight F.A.A. squadrons; total first line strength was 222 aircraft.

#### Control Transferred to Admiralty

On July 30, 1937, Neville Chamberlain (British prime minister) announced that complete control of the F.A.A. was to pass to the Admiralty, and the official title of the F.A.A. was changed to Air branch, R.N.; personnel became entirely naval; but opportunity to transfer to the Air branch was offered to R.A.F. personnel serving with the F.A.A. The Air ministry transferred four R.A.F. shore air bases to the Admiralty for the exclusive training of naval air personnel. In accordance with naval custom these stations were described as H.M. ships and given "ship" names in addition to their geographical names. The Admiralty at once began to train its own technical officers, previously lacking in the navy; but for a time the R.A.F. continued to provide preliminary flying training.

In April, 1938, to build up a trained reserve, the Admiralty opened a short service Air branch for commissioned officers, and on May 24, 1939, duality ended.

**SECOND GREAT WAR.** At the outbreak of war the Royal Navy had in commission eight aircraft carriers. The majority of these

were soon performing front-line service with the fleet in various theatres of war; H.M.S. *Courageous* was sunk by a U-boat in the first month. Flying equipment was scanty, and (by comparison with that of the R.A.F.) of inferior performance. Moreover, the value of naval aircraft was at first undervalued in many influential quarters.

The F.A.A. was first in the public eye when a single Seafox seaplane spotted for the naval guns at the battle of the River Plate, Dec., 1939; but with the growth of naval power and the increasing tempo of the war its work grew steadily more important to the strategists and more spectacular to the outside observer. The worth of the Fairey Swordfish (*q.v.*) torpedo bomber was demonstrated at Narvik in April, 1940. In June the *Glorious* was sunk, but the first of a new generation of fleet carriers, the *Illustrious* and the *Formidable*, were ready. Swordfish from the *Illustrious* achieved the historic attack on the Italian fleet at Taranto (*q.v.*), Nov. 11, 1940, while *Albacores* and Swordfish flown from the *Formidable* contributed to the British naval victory of Matapan (*q.v.*), Mar. 28, 1941.

Another action in which the F.A.A. cooperated notably with other forces was the sinking of the German battleship *Bismarck* (*q.v.*) in April. This was one of the outstanding events in the career of H.M.S. *Ark Royal* (*q.v.*), last carrier launched before the war. A glorious failure was the attempt by a squadron of Swordfish, led by Lt. Cdr. E. Esmonde (awarded a posthumous V.C.) to destroy the *Gneisenau* (*q.v.*) and the *Scharnhorst*, Feb., 1942. The crippling attack on the *Tirpitz* by the then new Fairey *Barraouda* dive-bombers (April 3, 1944) was more successful.

The escorting of convoys to Malta and Russia, and the introduction on a large scale of merchant aircraft carriers and "pocket" escort carriers (largely U.S.-built) called into being the two-seat Fairey *Fulmar*, and the single-seat *Sea Hurricane*, and soon afterwards the *Seafire*, little slower than the *Spitfire*.

It was found that carrier-borne aircraft, despite the apparent vulnerability of their "base," were essential

to any large-scale "task force," and design and production of naval aircraft were given a proper priority. The most successful U.S. designs—Grumman *Wildcat*, *Hellcat*, the torpedo-carrying *Avenger*, the Vought *Corsair*—also appeared in large numbers under the flag of the Royal Navy, and a further Fairey naval aircraft (the *Firefly* two-seat fighter) reached squadron service.

Personnel, ships, and aircraft of the Fleet Air Arm played a supporting but vital role in the invasion of France, from north and south, in 1944, and continued to operate extensively from shore bases, particularly in minelaying.

The British Pacific Fleet, formed late in 1944 for the final assault on Japan, included several fleet carriers, notably the *Illustrious*, and four of the new light fleet carrier class. The *Indefatigable*, the *Victorious*, and the *Formidable* were all hit by Japanese suicide bombers, but survived the last savage battles, and earned high praise from the U.S. commander-in-chief. The British carrier force destroyed 148 enemy aircraft and sank 108 ships in the 42 days preceding the surrender of Japan.

The total personnel of the R.N. Air branch then numbered over 70,000, and the strength in first-line aircraft had increased from 340 to about 1,500. In 1946 it was announced that the organization would in future be officially termed Naval Aviation. See *Royal Naval Air Service*; *Royal Navy. Consult Fleet Air Arm* (H.M.S.O.), 1943; *The Fleet Air Arm*, J. Moore, 1943.

**Fleet Prison, THE.** Former prison of old London. Its history has been traced back to the 12th century. Named after the Fleet river, it stood on the E. bank of that stream, S. of Fleet Lane, was burnt in the Great Fire, rebuilt, destroyed in the Gordon riots of 1780, rebuilt again in 1781-82,

Fleet Prison. The inner court, with prisoners engaged in a game of raquets

From a drawing by Rowlandson & Pugin, 1807

purchased by the City Corporation in 1844, used as a stone yard, and sold in 1864 to the L.C. & D.R. On part of the site was erected the Memorial Hall. The prison was used for prisoners of the Star Chamber, and later for debtors and bankrupts. The register books are preserved at Somerset House.

The poet Surrey, Bishop Hooper, Thomas Nash, Donne, Falkland, Prynne, James Howell, Wycherley, and Richard Savage were among notable prisoners here; as, among literary creations, were Falstaff, Mr. Pickwick, and Shandon, the shiftless journalist of Thackeray's *Pendennis*. Here, and in the liberties, clergymen imprisoned for debt celebrated clandestine marriages, between 1614 and 1754, when they became illegal. Favoured

29, 1940) and S. Dunstan in the West, the remains of Clifford's Inn and the second Serjeant's Inn, part of the Law Courts, entrances to the Temple (*q.v.*), and, near to the last-named, a restored timber house of 1610, the projecting upper storey of which, called Prince Henry's Room, is described as the council chamber of the duchy of Cornwall in the time of James I.

Chiefly on the N. side of Fleet Street are lanes, courts, and squares, e.g. Chancery Lane, Fetter Lane, Shoe Lane; Bolt Court, Crane Court, Wine Office Court, Johnson's Court, Red Lion Court; Gough Square. To the S. are Old Mitre Court and Salisbury Square. Whitefriars Street reminds the passer-by of the Carmelite monastery which once stood near. The Cheshire Cheese, Cock, Peele's, and Rainbow represent taverns and coffee houses of an earlier day. The site of the old Mitre tavern of Johnson's time is covered by Hoare's Bank, and that of the Devil tavern by Glyn Mills (Child's) Bank.

Known as the street of ink, from its associations with newspaper offices, the street contains the superb modern offices of the Daily Telegraph, the unusual steel and glass building of the Daily Express, the fine modern block housing Reuters,

and the London offices of most of the provincial, Empire, and foreign journals. The Great Fire of 1666 extended to Clifford's Inn on the N. side and to the Temple on the S. side, and after it the street was virtually rebuilt.

Wynkyn de Worde, the printer, worked at No. 32, near Temple Bar; Richard Tothill had his printing office in Fleet Street, and here Gorboduc, the first English tragedy, was printed and published. Punch offices, formerly at the N.W. corner of St. Bride's Avenue, were moved to Bouverie Street. At No. 32 John Murray the first published Byron's *Childe Harold*, and John Murray the second the early numbers of the *Quarterly Review*. Samuel Richardson had a house

in Salisbury Court. Michael Drayton and Cowley lived in Fleet Street; Samuel Johnson in Bolt Court, Johnson's Court, and Gough Square. Defoe stood in the pillory within Temple Bar in 1703. Izaak Walton lived on the N. side. The legend of Sweeney Todd, the demon barber, originated in a tale published in 1840. London's first pillar-box was put up at Ludgate Circus in 1855. Outside St. Dunstan's is a bust of Lord Northcliffe, and Edgar Wallace is commemorated by a plaque in Ludgate Circus where he once sold newspapers, while a bust of T. P. O'Connor is on the façade of Chronicle House.

**Bibliography.** *Annals of Fleet Street*, E. B. Chancellor, 1912; *Fleet Street in Seven Centuries*, W. G. Bell, 1912; *A Londoner's London*, W. Whitten, 1913; *Street of Ink*, H. Simonis, 1917.

**Fleet Train.** British naval supply and maintenance organization formed early in 1945 to supply and repair units of the British Pacific fleet in operations against the Japanese. The fleet train enabled warships to put in the maximum amount of service at sea without having to return to shore bases for refuelling and repairs, and was, in effect, a floating industrial seaport. Consisting of over 100 ships of 30 specialised types, it could feed, water, fuel, and munition ships of all categories at sea, carry out action repairs to all types from destroyers to battleships, and transport drafts up to 1,000 men a month.

**Fleetwood.** Mun. borough, seaport, and holiday resort of Lancashire, England. It stands at the

mouth of the Wyre, on Morecambe Bay, 8 m. N. of Blackpool, with a rly. station. It owes its name to Sir P. H. Fleetwood, who built quays and rlys.,

Fleetwood arms

and planned the town in 1836. It has regular steamer service with the Isle of Man, and carries on a brisk coasting trade. The third largest fishing port of the British Isles, it also produces salt for export.

In planning Fleetwood as a holiday resort, every advantage has been taken of the marine views. On the golf course every hole is in sight of the sea, and there are bowling and putting greens on the four-mile promenade. There are a sandy beach, swimming pool, boating lake, and model yacht pond.

Fleet Street. View looking east to S. Paul's. The spire of S. Bride's, which survived German incendiaries, is seen on the right; the projecting clock, left, belongs to the Daily Telegraph building

debtors were allowed to live in what was known as the rules or liberty of the Fleet, which included the N. side of Ludgate Hill and the Old Bailey to Fleet Lane and Market, and along the E. bank of the Fleet to what is now Ludgate Circus. *Consult* The Fleet: River, Prison, and Marriages, J. Ashton, 1888; The Chaplain of the Fleet, W. Besant and J. Rice, 1881.

**Fleet Street.** London thoroughfare in Farringdon Ward Without. Running W. from Ludgate Circus to Temple Bar, its precincts are closely associated with the ecclesiastical, legal, insurance, banking, publishing, and printing activities of the metropolis. It contains two churches of note, S. Bride's (burnt out in the German fire raid of Dec.

Fleetwood, Lancs. Quays and the promenade, which is four miles long and is bordered by bowling and putting greens and other watering-place amenities

The corporation has provided a marine hall, with ballroom, theatre, and restaurant. Pop. 25,000. Rossall School lies 3 m. S.

**Fleetwood, CHARLES** (d. 1692). English soldier. A younger son of Sir Miles Fleetwood, of Northamptonshire, he was trained for the law. He joined the parliamentary army at the outbreak of the Civil War and afterwards commanded a regiment. In 1646 he entered the house of commons as M.P. for Marlborough. He went with Cromwell into Scotland in command of the horse, and was present at Dunbar and Worcester, being at the time of the latter battle in command of the troops in England. Fleetwood was next commander-in-chief in Ireland, 1652-55, being also lord deputy until replaced by Henry Cromwell. Fleetwood was one of Cromwell's ten major-generals, and sat in his house of lords. He was commander-in-chief when Monk entered London, but he hesitated, and was lost; he did not go over to Charles II, while parliament took from him his command. Though he had taken no part in the trial of Charles I, he was exempted from a complete pardon at the Restoration. He died Oct. 4, 1692. In religion a Baptist, Fleetwood was a zealot, without any of the graces of some of the Puritans. He married in 1652 Cromwell's daughter Bridget, but their relations with the Protector were not uniformly cordial.

Charles Fleetwood, English soldier  
After Walker

**Fleg, EDMOND** (b. 1874). French author. Born at Geneva of Jewish parents, he served with distinction in the First Great War. His poem *Le Mur des Fleurs*, 1919, was

translated by Humbert Wolfe as *The Wailing Wall*. It was followed in 1922 by *Écoute Israël*, which presents the history of the Jewish race in epic style, using free rhythms. Other poems include *Le Psaume de la Terre Promise*; *Eternel est Notre Dieu*; *Apocalypse*. Fleg was also an outstanding playwright, wrote a successful novel, *L'Enfant Prophète*, and lives of Moses, Solomon, and Jesus (the last as told by the Wandering Jew). His personal manifesto, *Pourquoi Je Suis Juif* (trans. V. Gollancz, *Why I am a Jew*), was, like all his work, inspired by pride of race.

**Flegel, EDUARD ROBERT** (1855-86). German traveller. Born at Vilna, Oct. 1, 1855, he was appointed to a commercial post at Lagos in 1875, and in 1879 surveyed the Benue river. In 1880 he ascended the Niger to Gomba and in 1882 discovered the source of the Benue. Returning to Europe, he made another expedition, backed by Bismarck, to secure the Benue-Niger district for German trade, but was forestalled by the British Niger Co. He died on the coast at Brass, Sept. 11, 1886.

**Fleischer, DAVE** (b. 1894). American film cartoonist and director. Born in New York, July 14, 1894, he was educated at the Cooper Union, and in 1920 created and directed a series of animated cartoons for the Bray studios. His initial cartoon series, *Out of the Inkwell*, depicting the adventures of Koko the clown, was among the earliest of its kind in the silent film. His later creations included *Betty Boop*, the doll, and *Popeye the sailor*. His full-length films in colour, *Gulliver's Travels* and *Mr. Bug (or Hoppity) Goes to Town*, though indebted to the work of Disney (*q.v.*), were notable contributions to the art of film cartoon. Fleischer became head cartoonist to Columbia Pictures in 1942.

**Fleming, SIR ALEXANDER** (b. 1881). British pathologist. Born at Darvel, Ayrshire, he was educated at Kilmarnock academy and S. Mary's Hospital. After serving with the R.A.M.C. in the First Great War, he became professor of bacteriology at S. Mary's, discovering lysozyme in 1922. Fleming realized the possibilities of penicillin (*q.v.*) in 1929, and his research made possible its widespread use in modern medicine and surgery. He became F.R.S. in 1943, received a knighthood in 1944, was awarded the Nobel prize for medicine in 1945, and received the Albert gold medal of the Royal Society of Arts in 1946.

Sir Alexander Fleming, British pathologist

**Fleming, DAVID HAY** (1849-1931). Scottish historian. Born at St. Andrews, May 9, 1849, he was educated at the university there, and published a guide to the city in 1881. He devoted himself to Scottish history from 1888, and among his publications were *Scotland after the Union of the Crowns*, 1890; *Scottish History and Life*, 1902; *Scottish Reformation*, 1903. He died in Nov., 1931, and his work was the subject of a study by H. M. Paton, 1934.

**Fleming, SIR JOHN AMBROSE** (1849-1945). British physicist and engineer. He was born at Lancaster, Nov. 29, 1849, and educated in London at University College and the Royal College of Chemistry. He was a science master at Cheltenham in 1874, and worked at Cambridge under Clerk-Maxwell, 1877-81. Then he went to University College, Nottingham, as professor of physics and mathematics, returning to London in 1885 as professor of electrical engineering at University College, remaining until 1926. He also acted as adviser to the Edison Electric Lighting Co.

Sir Ambrose Fleming, British physicist and engineer

Fleming was associated with the introduction into Great Britain of the telephone, electric lighting by incandescent lamps, and wireless telegraphy. He invented the thermionic valve that revolutionised the practice of wireless, and other

branches of electrical engineering are indebted to him for improvements in method and apparatus. He was elected F.R.S. in 1892 and received a knighthood in 1929. Among his books are *Fifty Years of Electricity*, 1921; *Electrons, Electric Waves, and Wireless Telephony*, 1923; *Memories of a Scientific Life*, 1934. He died at Sidmouth, April 18, 1945.

**Fleming, MARJORY** (1803–11). Scottish infant prodigy. Born Jan. 15, 1803, a niece of Mrs. Keith of Ravelston, at whose house Scott frequently saw her, she read history at the age of six and wrote diaries and poems. She died Dec. 19, 1811. Her journals, letters, and

Marjory Fleming  
After a water-colour  
by I. Keith

verses were collected in 1934; and a biography by O. Malet appeared in 1946. John Brown includes an essay on her in *Horae Subsecivae*.

**Fleming, PETER** (b. 1907). British journalist. Born May 31, 1907, he was educated at Eton and Christ Church, Oxford, and joined the Grenadier Guards. Some racy and unconventional travel books, e.g. *Brazilian Adventure*, 1933; *News from Tartary*, 1936, brought him a public, and he became an assistant editor and leader-writer on *The Times*. He was later a war correspondent in Norway, 1940, and Greece, 1941. He married the actress Celia Johnson in 1935.

**Fleming, SIR SANDFORD** (1827–1915). Canadian engineer. Born at Kirkcaldy, Fife, Jan. 7, 1827, he went to Canada and became connected with rly. construction about 1846. After 1871 he surveyed and constructed the Inter-colonial line, and afterwards he surveyed a route through the Rockies for the C.P.R. He advocated an imperial cable system and standard time. Made a K.C.M.G. in 1897, he died July 22, 1915.

**Flemings.** Name given to the inhabitants of Flanders. A small sect of early Protestants, influenced by the Mennonites, were called Flemings or Flandrians about the middle of the 16th century. Now numbering 4,500,000 and inhabiting the west of the country, Flemings form slightly over half the population of Belgium. In the First Great War most cooperated loyally against the Germans, but behind the German front a group of Flemish

nationalists supported the occupying power. Pardoned by the Belgian government after the armistice, they continued to demand autonomy and achieved a number of concessions. Radical Flemish nationalists envisaged the union of Flanders with the Netherlands and spoke of Dutch and Flemish forming one nation called *Dietsch*. Germany claimed the Flemings as members of the Germanic family, and with the rise of Hitler, Nazi propaganda was considerable in the region. Flemish influence was responsible for Belgium's detachment from France and return to the policy of neutrality before the Second Great War. The fifth column which assisted Germany in the invasion of Belgium in 1940 was largely composed of Flemings.

Flemish immigrants to England have frequently played a part in English and Welsh history. Chroniclers speak of Tostig having Flemish auxiliaries under his flag at Stamford Bridge, 1066. Henry I settled a number of Flemings in Dyfed, S. Wales, about 1108; they were long the objects of Welsh hostility. In the battle with the S. Wales marchers at Teifi Ford, near Cardigan, in 1136, numbers of these settlers were slain. Other attacks on them in 1144 and 1164 were avenged by their harrying of Iscold or Lower Gwent in 1165. Strongly attacked by the Welsh

leader Maelgwyn Gwynedd, 1188, they made submission to Llewellyn I in 1217. Flemings influenced the growth of the woollen and weaving industries in England, especially in E. Anglia. *See Flanders.*

**Flemington.** Suburb of Melbourne, Victoria. It is 3 m. N. of the city and has a fine racecourse, founded 1861, on which is run the race for the Melbourne Cup.

#### Flemish School OF PAINTING.

Distinctive type of art which emerged in Flanders in the 15th century, particularly at Bruges, Ghent, and Antwerp. The earliest phases at the first two are still obscure. The first names to emerge are those of the Limburg brothers, illuminators, of Maaseyck. Next come the brothers van Eyck, Hubert (c. 1366–1426) and Jan (c. 1385–1440), usually considered the founders of the school and certainly its main inspiration. Their Ghent altar-piece, *The Adoration of the Lamb* (*see illus.* page 3227) begun by Hubert in 1420, completed by Jan in 1432, helped to establish the predominance of the Flemish style of painting in N. Europe. If they did not invent oil-painting, they were the first to reveal its full possibilities and so to improve its technique as to make it virtually a new medium; and this is one of the great contributions of the Flemish school to the history of art, though the secret of the van Eycks' own perfection of the medium appears to have died with them.

Notable names among the following generation of painters are the so-called *Maitre de Flammelle* (possibly Robert Campin), Jacques Duret, Roger van der Weyden, Dierick Bouts, and Petrus Christus. A little later were Hans Memlinc, Hugo van der Goes, Gérard David, and Quinten Matsys. These were all religious painters. Their contemporaries included Jerome Bosch, the earliest satirist, and Patinir, one of the first landscape painters.

Flemish School. Madonna and Child Enthroned,  
by Dierick Bouts (c. 1410–75)  
National Gallery, London

Flemish School. Massacre of the Innocents, by Pieter Bruegel the Younger, typical of detailed composition of the 16th century Flemish painters. This picture, in the museum at Brussels, is an exact copy of one by P. Bruegel the elder in Vienna

In the work of these Flemish primitives the true Gothic spirit found expression. They record the intensity of the Gothic conception of the Christian drama, and reflect the desire for richness and elaboration of detail inseparable from the Gothic ideal. No Italian master rivalled them in this respect; nor, when Flemish technique was practised in Italy, could any southern painters attain their brilliance and delicacy. The Flemish technique, derived from missal illumination, was unsuited to the large demands of wall decoration which engrossed the Italian painters. But the influence of the Flemish masters of the 15th century on the art of Germany, Spain, and Portugal was important, and in England, especially in East Anglia, Flemish painters had considerable business.

A new phase entered with Jan Mabuse (1472-1532), who studied in Italy and introduced an alien note into the native vision. The rococo period of excessive elaboration with no compensation in the way of serious interpretation is represented by van Orley, Mostaert, and Engelbrechtsen; and rather more happily by Lucas van Leyden and Scovel. In this period the satirical genre picture, indi-

genous to the Low Countries and later developed by the Dutch painters, was first introduced, well-known examples being the Moneylenders and Misers of M. van Reyerswael. The greatest genre painter of the school, the last and

the most original of all the Primitive masters, was Pieter Bruegel (1526-1569), the only one to achieve a mural largeness of style, yet retain animation and humour.

Flemish painting reached its full flowering in the 16th and early

17th centuries with the emergence of its outstanding exuberant and prolific genius, Rubens (1577-1640) and his pupils and disciples, chief of whom was van Dyck. The notable masters of this final period include Cornelius de Vos, portrait painter; Paulus de Vos and Snyders, animal painters; Jakob Jordaens, best described as a lesser Rubens; and David Teniers, who might with equal justice be called a minor Bruegel, and whose lively work forms a

Flemish School. A Canon with Patron Saints, by Gerard David (c. 1450-1523), a pupil of Hans Memling  
National Gallery, London

link between the Flemish and Dutch genre painters.

It should be noted that until the clear emergence of a distinctive Dutch school at the end of the 16th century, Flemish art and Dutch art were running on parallel lines and no precise labelling of individual painters as Flemish or Dutch is practicable. This occasionally causes confusion, and use of the broader term "Netherlands school" does not help. It is perhaps simplest, as it is also broadly correct, to describe the 15th and 16th century genius as Flemish and that of the 17th century as Dutch. After the 15th century there was no Flemish school as such.

**Bibliography.** The Flemish School of Painting, A. J. Wauters, Eng. trans. H. Rossell, 1885; Anciens Arts de Flandre, E. Durrand-Gréville, 1905; La Peinture en Belgique, H. Fierens-Gevaert, 1909; Art in Flanders, M. Rooses, 1914; Flemish Painting, E. Cammaerts, 1945.

**Flensburg.** Seaport of Slesvig, Germany. It lies at the S. extremity of the Flensburg Fjord, about 23 m. N. of Slesvig town. Beautifully situated on the steep shores of the land-locked fjord, it has a good harbour, with shipyards, foundries, breweries, and bicycle works as its industries. Whaling vessels in peace-time left annually for the Greenland fisheries. Originally founded during the 12th century, Flensburg has several fine old buildings, notably the churches of S. Nicholas (14th century) and S. Mary (13th century). Formerly a Danish town, it was entered by German troops Feb. 7, 1864, and annexed with Slesvig. The Slesvig-Holstein plebiscite after the First Great War gave a large majority for German rule. The shipyards and torpedo school were heavily bombed in the Second Great War. Here, after Hitler's death, Admiral Doenitz set up his "government," May 1, 1945; and here Doenitz, his "ministers," and the German high command were arrested, Mar. 23, by the Allies. Pop. 66,580.

**Flers.** Town of France, in the dept. of Orne. It stands on the Vère, 40 m. S. by W. of Caen. It has a 16th century château, and cotton spinning, bleaching, and dyeing works. It was entered by the British 2nd army Aug. 16, 1944. Pop. 12,336. *Pron.* Flare.

**Flers, ROBERT DE LA MOTTE-ANGO, MARQUIS OF (1872-1927).** French dramatist. Born at Pont-l'Évêque, Nov. 22, 1872, and educated at Paris, he made his reputation as collaborator with

G. A. de Caillavet in a series of light and witty comedies. Among them are *Les Travaux d'Hercule*, 1901; *Primerose*, 1911; *L'Habit Vert*, 1912; *La Belle Aventure*, 1913. He became editor of *Le Figaro*, with Alfred Capus, in 1914; he resigned this post in 1920, rejoining the paper in 1922. He died July 30, 1927.

**Fleshly School of Poetry, THE.** Derisive name given to certain 19th century poets, chiefly D. G. Rossetti and A. C. Swinburne. It originated in an article in *The Contemporary Review*, entitled *The Fleshly School of Poetry and Other Phenomena of the Day*, by Thomas Maitland (Robert Buchanan), which was afterwards published as a pamphlet, 1872. Swinburne replied in *Under the Microscope*, 1872. Buchanan later made a full *amende honorable* in regard to Rossetti's work.

**Fletcher, ANDREW, OF SALTOUN (1655-1716).** Scottish politician. Born at Saltoun (now Salton), East Lothian, he was educated by the parish minister, Gilbert Burnet, afterwards bishop of Salisbury. He sat as a commissioner in the Scots convention of estates in 1678, and vigorously opposed the government. In 1685 he joined Monmouth's expedition to England, but, having killed a man in a private quarrel, fled to Spain. He returned in 1688 with William of Orange, and became a determined opponent of the Union. He is remembered by the remark from his *Account of a Conversation*, "I knew a very wise man, so much of Sir Christopher's (Sir Christopher Musgrave's) sentiment, that he believed if a man were permitted to make all the ballads, he would not care who should make the laws of a nation." Fletcher set up the first barley mill in the British Isles.

Andrew Fletcher,  
Scottish politician  
After Allan

**Fletcher, SIR BANISTER FLIGHT (b. 1866).** British architect. Born in London, Feb. 15, 1866, he was educated at the Royal Academy schools and London university, at which he was lecturer and assistant professor (King's College) and university staff lecturer on architecture. President of the R.I.B.A., and for many years partner in the firm of architects which bore his name, he was knighted in 1919. His publications include

his great *History of Architecture on the Comparative Method*—a standard work; *Andrea Palladio*; *The Influence of Material on Architecture*; *The English Home*.

Sir Banister Fletcher,  
British architect

**Fletcher, GILES (c. 1588-1623).** English poet. Brother of Phineas and cousin of John Fletcher, the dramatist, he was educated at Westminster and Cambridge, and died rector of Alderton, Suffolk. His principal work, an allegorical poem entitled *Christ's Victory and Triumph*, 1610, was modelled on Spenser's *Faerie Queene*, and influenced Milton.

**Fletcher, SIR HENRY (1727-1807).** British politician and administrator. Born in Cumberland, he served the E. India Co. from boyhood in capacities ranging from sea-captain to director, 1769-87, and chairman, 1782-83. Whig M.P. for Cumberland, 1786-1806, he received a baronetcy in 1782. He supported Fox's proposals for administrative reforms in India and Grey's measure for parliamentary reform; and was highly regarded for his personal character and liberality. He died March 25, 1807.

**Fletcher, HANSLIP (b. 1874).** British artist. Born in London, he was educated at Merchant Taylors'. He became well known for his line-drawings and etchings of London, which appeared in four volumes entitled *Changing London*. Under this title he contributed from 1923 a weekly series of topographical drawings to the *Sunday Times*. His work was purchased by the Walker Art Gallery, Liverpool, the National Museum of Wales, and London Guildhall library.

**Fletcher, JOHN (1579-1625).** English poet and dramatist. Son of Dr. Richard Fletcher, bishop of London, he was born at Rye, and educated at Bene't (Corpus Christi) College, Cambridge. On his father's death, being left without means, he took to writing for the stage, collaborating about 1607 with Francis Beaumont and others in plays which

John Fletcher,  
English dramatist  
From an old engraving

introduced tragi-comedy to the English theatre. Independently he wrote fifteen plays, including *The Faithful Shepherdess* (a beautiful pastoral play), *Valentinian*, *The Wild-Goose Chase*, *Monsieur Thomas*, *Woman's Prize* (a sequel to *The Taming of the Shrew*), *A Wife for a Month*, and *The Chances*. He also collaborated with Massinger, Middleton, Rowley, Field, and Daborne.

To what extent Fletcher was responsible for *The Two Noble Kinsmen* and Henry VIII remains a vexed question. He wrote beautiful lyrics and some of the raciest dialogue in English dramatic literature, and the free movement of his blank verse is a clue to his contribution to plays partly written by others. He died of the plague and was buried Aug. 29, 1625, in S. Saviour's, Southwark. See Beaumont, F.; consult also John Fletcher, O. L. Hatcher, 1905.

**Fletcher, Sir Lazarus** (1854-1921). A British mineralogist. Born at Salford, March 3, 1854, he was educated at Manchester grammar school and Balliol College, Oxford. Appointed a demonstrator in the Clarendon Laboratory, he remained lecturing in Oxford until 1890, when he became keeper of minerals in the natural history department of the British Museum. He was promoted director of the department in 1909, and resigned in 1919. In 1916 Fletcher was knighted, and his many honours included the F.R.S. From 1888 to 1909 he was secretary of the Mineralogical Society. He wrote *Introduction to the Study of Minerals*, 1884; *Introduction to the Study of Rocks*, 1895. He died Jan. 6, 1921.

**Fletcher, Phineas** (1582-1650). English poet. Phineas was brother of Giles Fletcher and, like him, an imitator of Spenser. He died rector of Hilgay, Norfolk. His works have been edited by Grosart, 1868, the most important being a poem of 4,800 lines entitled *The Purple Island*, an extraordinary allegory of the human body.

**Fletchers' Company, THE.** City of London livery company. Of ancient origin and associated with

Fletchers' Company arms

the Bowyers, the Fletchers (Fr. *flèche*, an arrow) is a company by prescription, not charter, was granted arms in 1427, and possessed a hall in St. Mary Axe. The old records

have been lost, the earliest extant being dated 1775. The offices are at 33, St. Mary-at-Hill, E.C.3.

**Fleur-de-Lis** (Fr., lily-flower). In heraldry, an extremely ancient symbol. Found among Egyptian hieroglyphics and used by the Anglo-Saxon kings, it was probably a conventional representation of some such flower as the lotus, riverside flags or the iris. It consists of a central bulbous

Fleur-de-Lis in heraldry

petal and two side-curving petals, a fillet and a stalk, usually triparted. The fleur-de-lis, an early cognizance of the Carolingian kings, became identified with the royal houses of France, who bore the golden flowers on a blue shield.

At first the shield was strewn with the lis, but occasionally only three appeared, some say in allusion to the Holy Trinity, a fashion which became permanent under Charles VI. The French arms (azure, semée de lis d'or) was quartered with the arms of England by Edward III; Henry IV reduced the number of lis to three, and after the treaty of Amiens and the Union with Ireland in 1801, the French quartering was omitted from the arms of the English royal family. *Pron.* Fler-de-leess.

**Fleurus.** Town of Belgium, in the prov. of Hainault. It stands in a plain, 8 m. N.E. of Charleroi, and is a junction for the rly. to Gembloux, Landen, and Nivelles. There is a steam tramway to Namur. Four important battles have been fought near this small Belgian town. In the first the duke of Brunswick defeated the Spaniards under Cordova, Aug. 29, 1622. Under Marshal Luxembourg the French gained a victory over the allied Spanish, Dutch, and Germans, July 1, 1690. On June 26, 1794, the French under Jourdan inflicted a crushing defeat upon the Austrians and forced them to evacuate Flanders. Napoleon here defeated the Prussians, June 16, 1815, in the battle usually known as the battle of Ligny (*q.v.*).

**Fleury, Flory, or Flowery.** In heraldry, any charge decorated

Fleury, in heraldry

with fleur-de-lis. Examples are crosses at the ends of the limbs or in the angles, on the tressure, and on scapulars, etc. See Cross illus.

**Fleury, André Hercule de** (1653-1743). French statesman. Born at Lodève, Hérault, June 22, 1653, he was educated at Paris, took holy orders, and became chaplain to Louis XIV, who made him bishop of Fréjus in 1698, and tutor to the future king Louis XV. In 1726 he became chief minister of the latter and was appointed cardinal. His administration was upright and strictly economical, but he did nothing to check the early dissipations of the king or the abuses of the farmers-general.

de Fleury  
After Rigaud

His foreign policy was directed chiefly towards ensuring peace, and to this end he worked closely with the English minister Walpole. The French intervention in Polish affairs in 1733 was undertaken against his better judgement, but he failed to prevent France from being involved in the war of the Austrian Succession, 1740, and died discouraged and in ill-favour, Jan. 29, 1743.

**Fleury, Claude** (1640-1723). French church historian. Born Dec. 6, 1640, in Paris and educated there, he practised for nine years as an advocate, and then devoted himself to theology. In 1672 Louis XIV entrusted him with the education of the young princes, and he became nominally the abbot of Loc-Dieu and later prior of Argenteuil. From 1691 he was writing his *Ecclesiastical History* in 20 volumes. He died July 14, 1723.

**Flexner, Simon** (1863-1946). American pathologist. Born of Jewish parents at Louisville, Ky., March 25, 1863, he was educated at Johns Hopkins university, Baltimore, at which he became assistant to the professor of pathology, 1895. In 1899 he was appointed professor at Pennsylvania university. Joining the Rockefeller Institute, New York,

as director in 1903, he held the position until 1935, when he became director emeritus. Here he carried out studies of bacteria, germs, and serums, made experiments in the pathology of toxalbumin intoxication, produced in 1905 a serum for preventing death from cerebro-spinal meningitis, and discovered the dysentery bacillus. His work was recognized throughout the world, and he was Eastman professor at Oxford, 1937-38. Flexner died in New York, May 2, 1946.

**Flibbertigibbet** or **DICKIE SLUDGE**. In Scott's novel *Kenilworth* (q.v.), a mischievous but

ambitious dwarf, in league with Wayland Smith in deceiving the Berkshire villagers.

**Fliegende Blätter** (Ger. flying leaves). Oldest German humorous weekly paper, founded in 1844. It had little political satire from 1856, but excellent cartoons and stereotyped objects of jokes: the mother-in-law, the naughty little boy, the dandy, the arrogant lieutenant of the Guards. In 1928 it was merged with the *Megendorfer Blätter*, a similar family paper printed in colours. Both periodicals were published at Munich. The paper lapsed during the Nazi period.

than the wing area of the aeroplane, and their speeds are very much lower. The loading per square foot of wing surface of birds rarely exceeds more than three or four lb. and is generally considerably less; their speeds are of the order of 25 to 40 m.p.h. Speeds of 100 m.p.h. and over, which are sometimes attained by certain birds such as the swift and homing pigeon, are due to favourable winds. Radar and high-speed photography, used to measure the speed of birds, show clearly that this has frequently been grossly exaggerated in the past.

High speed photographic methods developed at the Massachusetts Institute of Technology and elsewhere indicate that the flexibility of the wings of birds and insects makes it possible for one of these creatures in flight to change its wing-shape considerably for differing conditions of flight, and still to keep full flying control.

The non-flapping flight (i.e. the ability to soar, sometimes for hours) of the albatross, vulture, and other birds, was studied for many years before it was understood. It is achieved without losing height by the use of rising currents of air. These are of two kinds, those due to wind and the varying contours of the ground, and those due to the upward movement of hot air.

## FLIGHT: BY INSECTS, BIRDS, AND MEN

J. Laurence Pritchard, Hon.F.R.Ae.S., Hon.M.I.Ae.S.

*Man sought to emulate the birds for centuries before he succeeded in leaving the earth's surface in a heavier-than-air machine. Here is a short account first of natural flight, and then of the development of the aeroplane by man. See also Aerodynamics; Aeronautics; Aeroplane; Airship; Glider; Jet Propulsion; Rocket Propulsion, etc.*

The power of flight is possessed by most birds and insects, also bats. They fly (all but bats) by flapping their wings, and as the bird or insect moves forward during flight the motion of the wing is not merely straight up and down, but slightly forward and backward also. The cardinal principle of flight is that the air must be forced downward in order that the bird or the insect can sustain its own weight in flight; or alterna-

tively that the air is forced upwards against the wings of the bird in flight. (The same principle applies to the aeroplane.) The amount of air which is moved in this way in a given time depends largely upon the surface area of the wings, the speed of the bird or insect, and the angle of the wings to the flight path. The areas of the wings of birds and insects, in proportion to their weight, are considerably greater

Flight. Diagrams illustrating the flight of a pigeon viewed from three points; A, from above; B, from the side; C, obliquely from side and front

After the diagram by E. J. Marey in "Movement," by permission of Wm. Heinemann

**FLIGHT BY MAN.** The story of man's attempts to fly, prompted by observation of flight in nature, is lost in mythology; but Leonardo da Vinci (*q.v.*) made the first serious study of its possibilities. At the beginning of the 19th century Sir George Cayley pointed out the importance of control and the necessity for an engine far lighter than any then existing, even predicting the coming of an explosion engine as a possible solution. The power-driven flying models made by Henson and Stringfellow some 50 years later made it clear that it was want of a

suitable motive power that was holding back flying. In the latter half of the century, experiments with gliders showed that these could be made to cover considerable distances, making use (like a soaring bird) of rising currents of air. The German Lilienthal (*q.v.*) constructed an artificial hill outside Berlin from which he carried out experiments, and Pilcher (*q.v.*) in Great Britain constructed a number of gliders in which he flew. Sir Hiram Maxim (*q.v.*) built a huge machine which, driven by a steam engine, lifted several thousand pounds before it was wrecked and abandoned.

By 1898 Professor Langley in the U.S.A. decided that he could build an aeroplane using the internal combustion engine (*q.v.*) as motive power. An American engineer, Manley, produced an engine developing 50 h.p. which weighed only 120 lb. A first attempt at flight in Langley's aeroplane was made in Oct., 1903, a second in December. Both failed. Later knowledge has made it clear that the machine (preserved at the Smithsonian Institution) could not have flown. On Dec. 17, 1903, however, Orville Wright (*q.v.*) made the first powered flight under full control in a machine constructed by him and his brother Wilbur, before building which they had carried out experiments in a primitive wind tunnel, and many gliding experiments in steady winds.

The Wright brothers, like others before them, realized the importance of knowing how much a given surface would lift at a given speed, and how much would be the

resistance of the air to the surface at that speed. Many attempts to glide and fly had failed because they were based on inaccurate figures. The Wrights tested all kinds of planes, and they found that a plane which is curved, as are the wings of birds, gives a considerably greater lifting power, in proportion to its resistance,

Flight. Diagram of the forces acting on an aeroplane in horizontal flight. T, the thrust of the propeller; L, the lift on the wings; W, the weight of the aeroplane; D, the resistance or drag; and P, the force on the tail plane to maintain equilibrium

than does a flat plane. The fitting of wings to a structure, however, even if they give sufficient lift, does not ensure safe gliding or flying. For complete safety in the air, it would be necessary to control the motion of the machine used in three directions, a problem yet to be fully solved at very high or very low speeds. Lilienthal, Pilcher, and many other early experimenters were killed when they lost control of their gliders. The Wright brothers fully realized the dangers ahead of them, and provided controls to the best of their knowledge at the time.

In the normal type of aeroplane there are four controlling units, the engine, the elevators, the rudder, and the ailerons. The elevators are movable parts on the tail surface which can be moved up and down and so alter the angle at which the aeroplane is flying, and therefore its speed. The rudder applies the force necessary to make an aeroplane turn. Unless the aeroplane is correctly banked on the turn it will side-slip, and the function of the ailerons, which are movable parts of the wings, is to obtain the correct banking angle and prevent side-slipping. Aeroplanes have been built and successfully flown without tails or rudders, but they have had alternative mechanisms. Their wings are swept back, and

they have the necessary movable control surfaces on the wing tips.

The theory of the control of an aeroplane under varying conditions of flight is comparatively simple, but the difficulty of putting theory into practice has increased in complexity as speed has increased, increasing the compression of the air on the leading edge of the wing. The flow of air over the wings and body of an aeroplane varies with the speed of the aeroplane and also with the angle at which the wings or the body are meeting the air. No one has yet succeeded in predicting by theoretical methods the form of air flow, although close approximations have been made.

One of the difficulties of the control of aeroplanes at low speed is to keep the air flow smooth over the wing. If the smooth flow begins to break up, the lift is decreased and the resistance increased until "stalling point," when the aeroplane may become completely out of control. A valuable invention to delay onset of the stall was the Handley Page slot, which opens automatically on the wing when the wing begins to lose its lifting power and increases the lift at the moment the aeroplane most requires it.

The greater the speed of the aeroplane, the greater the air resistance, and the higher the h.p. required to force the aeroplane through the air. Flying at great heights, where the air is more rarefied, simplifies this particular problem, but introduces others, e.g. the necessity to provide suitable

Flight. Diagram showing how the stream of air is deflected by the curved wing, shown in section in black, of an aeroplane. The air is forced downwards at the rear or trailing edge of the wing, and a partial vacuum is created above the wing with increased pressure below it, so making it lift

air-pressure and temperature conditions for passengers and crews.

At high speeds the air breaks away from the wing differently from at low speeds, and a special shape of wing, known as a laminar flow wing, has been designed to delay the change as long as possible. These wings are, however, easily

affected by minute irregularities in their form or by dust on their surface. One of the great difficulties with high-speed flight is that of landing and taking off, for wings suitable for high speed are not suitable for the low speeds at which landing and taking off are safely effected. Nor are they as a rule suitable where high lift is wanted. This and other difficulties are increasing as speeds which will ultimately no doubt exceed that of sound (about 770 m.p.h. at sea level) are approached.

New methods of flight may solve some of the problems presented by aircraft with fixed wings. Machines with movable wings, such as the Cervo Autogiro and the helicopter, depend for their lifting power on wings which revolve somewhat like a horizontal airscrew of two, three, or more blades. These aircraft can land vertically, or nearly so, at very low speeds, rise vertically from a small area, and hover in the air over a given spot. Theory suggests that they will never fly at the high speeds of the fixed wing aeroplane; but the advantage of ability to land at a low speed in a small space is enough to encourage the development of moving wing aircraft to the utmost extent.

During the Second Great War, much work was done on jet and rocket propulsion as methods of moving aircraft. Rocket propulsion has two advantages: very high speeds—up to 3,000 m.p.h. could be attained with it—and it is independent of atmospheric conditions. The rocket, in fact, works better the higher it flies, as air resistance is lessened. Much the same is true of jet propulsion. Safe landing is the chief problem.

**Bibliography.** Bird Flight, G. C. Aymar, 1936; Biology of Flight, by F. L. Fitzpatrick and K. Stiles, 1942; Aircraft Design, C. H. Latimer Needham, 1939; Elementary Aerodynamics, N. A. V. Pierce, 1944.

**Flight Engineer.** Member of a bomber crew in the R.A.F. who is responsible for the correct functioning of the aircraft engines while in flight. A non-commissioned flight engineer is never of a lower rank than sergeant, while a commissioned flight engineer generally holds the rank of pilot officer or flying officer. A flight engineer's brevet, worn on the left breast of the tunic, consists of a half wing with the letter E.

**Flight Lieutenant.** Commissioned officer in the R.A.F. The rank is equivalent to a lieutenant

in the Royal Navy and captain in the army. The rank was originally introduced into the Royal Naval Air Service (*q.v.*), and when adopted by the R.A.F. was at first confined to officers actually engaged in flying duties, but is now held in all branches of the service. Rank is indicated by two spaced rings on the sleeve of the tunic or on the epaulettes of the greatcoat.

**Flight Mechanic.** Tradesman in the R.A.F. who is responsible for the overhauling of aircraft engines or aircraft frames on the ground. Flight mechanics either enlist in the service as fully qualified tradesmen or join as boy apprentices. They are the second highest paid tradesmen in the R.A.F., and classified in Group II.

**Flight Sergeant.** Non-commissioned officer in the R.A.F., ranking above a sergeant and below a warrant officer. He is equivalent in rank to a staff sergeant in the army and petty officer in the Royal Navy. He may be either in the flying branch of the service or engaged on ground duties. Rank is indicated by three stripes surmounted by a crown worn on the sleeve of the tunic.

**Flinck, GOVAERT (1615-60).** Dutch painter. Born at Cleves, Jan. 25, 1615, he was one of Rembrandt's most successful pupils. His earlier work, painted under the influence of the master, is of greater value than his later Italianate style of court painting. Notable works are The Annunciation to the Shepherds, Louvre; The Grey Bearded Man, Vienna; The Expulsion of Hagar, Berlin, painted for the elector of Brandenburg; The Civic Guard Fête, Amsterdam. He died at Amsterdam, Feb. 2, 1660.

**Flinders.** River of Queensland, Australia. It issues from Mt. Courtney in Douglas co., and flows S.W., W., and then N.W. for a total course of over 300 m., to discharge into the Gulf of Carpentaria, 10 m. S.W. of Kimberley. It was named after Matthew Flinders (*v.i.*), the navigator.

**Flinders, MATTHEW (1774-1814).** British sailor. Born March 16, 1774, at Donington, Lincs, the son of a surgeon, in 1790 he went to transplant bread-fruit trees from the South Sea Islands to the W. Indies. Returning in 1793, he was posted to the *Bellerophon*, saw action on the Glorious First of June (1794), and sailed in the *Reliance* to New South Wales, where he began a series of explorations lasting until 1799, circumnavigating Tasmania, which was hitherto supposed to be part of the mainland.

In 1800 Flinders was appointed to the *Investigator*, and again sailed (1801) for Australia, where he charted the Gulf of Carpentaria, and surveyed the coast of New Holland. On his voyage home, unaware that Great Britain and France were at war, he was detained by the French at Mauritius, and imprisoned, 1803. In 1810 he was released and made his way to England, where he wrote an account of his discoveries. He died July 19, 1814. His name survives in a river of Queensland, a mt. range of S. Australia, a bay of W. Australia, and an island N. of Tasmania.

**Flindersia.** Small genus of evergreen trees of the family Rutaceae. Natives of Australasia and the Moluccas, they have hard, close-grained wood of a yellow tint, useful for many purposes. *F. australis* (Crow's Ash), found in Queensland and New South Wales, grows to a height of 60 ft., with smooth, flaking bark, and alternate leaves broken into three to six oblong leaflets. The numerous small white flowers are in dense clusters. The wood is very durable. The trees are named after Matthew Flinders (*v.s.*).

**Flinders Range.** Mt. system of South Australia. It runs N.N.E. for about 200 m. from Spencer Gulf between Lakes Torrens and Frome, attaining 3,900 ft. in St. Mary's Peak. Uranium has been found in Mt. Painter.

**Flin Flon.** Town of Manitoba, Canada. Near the border of Saskatchewan, in lat. 55° N., it is a branch terminus of the C.N.R. and also served by airway. A mine at Flin Flon Lake has a daily output of 6,000 tons of high grade copper sulphide; power comes from Island Falls on the Churchill River, 56 m. to N.W. The opening of this pre-Cambrian area has transformed Manitoba from a purely agricultural to a partly industrial province. Pop. 7,000.

**Flint.** Crystalline mineral composed mainly of silica; a variety of chalcedony. It is compact, almost opaque, usually dark grey or brown, somewhat harder than steel, and breaks with a shell-like fracture, forming sharp-cutting edges. When first unearthed it is brittle, becoming toughened by

Matthew Flinders  
From an engraving

exposure. Chert and hornstone are coarser forms.

In Great Britain and W. Europe flint occurs mainly in the middle and upper Chalk formations, where it forms irregular nodules, tabular masses, and veins. It is also scattered through Tertiary gravels and alluvial soils, sometimes in great quantities, derived from disintegrated chalk rock. The nodules, sometimes several feet across, are often the silicified remains of sponges, or are hollow shells formed by the concretion of gelatinous silica around urchins, sponges, and other marine organisms. When this dense, non-crystalline constituent, the cause of black flint, is removed, white flint results. The veins were deposited in joints and fissures in chalk rock, carbonate of lime being displaced by dissolved silica of organic origin.

The cutting edge produced by flaking enabled palaeolithic man to invent edged tools, before the introduction of metallurgy. Utilising at first water-worn pebbles or cliff-exposed nodules, this industry led to flint-mining. The discovery that sparks are produced when flint is struck with iron pyrites brought about the percussive method of fire-making. In medieval E. Anglia flint was largely used in church-building, walls being made of undressed or split flints, and porches and battlements panelled with squared flints, sometimes in beautiful colour zones. As road metal it is unsatisfactory because of its readiness to pulverise. Some flint is utilised for pottery and optical or flint-glass. A snow-white quartz powder is obtained by heating flints and throwing them into cold water. In France they are crushed between chert blocks and exported to Great Britain and America. In Essex and the home counties S. of the Thames and in Belgium there is normally a large output, much used in pottery. See Chalk; Flint Implements.

**Flint.** Mun. bor., formerly the county town of Flintshire, Wales. It stands on the S. shore of the Dee estuary, 12 m. N.W. of Chester on the railway. It was once an important harbour, but the accumulation of sand in the estuary now keeps the tidal waters away from the town. Hundreds of acres of marshland in the estuary could be

profitably reclaimed. Artificial silk is made here. There are alkali and copper works, and lead and coal mines in the neighbourhood. The castle, built by Edward I, was the scene of the meeting between Richard II and Bolingbroke, described by Shakespeare, and was twice captured by the parliamentarians and dismantled in 1647. It was taken over by the office of works in 1920. Market day, Sat. Pop. est. 13,050.

**Flint.** City of Michigan, U.S.A., the co. seat of Genesee co. It stands on Flint river, 70 m. by rly. N. by W. of Detroit, and is served by rlys. and an airport. Ranking second in the world to Detroit in production of motor cars, Flint contains the plants of several subsidiaries of General Motors. It developed this prominence from an earlier output of buggies, carriages, and carts. Flint trebled its population during 1900-10. Other manufactured goods include iron products, bricks and tiles, cigars, and flour. Pop. 151,543.

**Flint.** River of Georgia, U.S.A. Rising in the N. part of the state, it flows 350 m. generally S.W. to unite with the Chattahoochee in forming the Apalachicola. Navigable for most of its length, it drains an area of 8,000 sq. m. A hydroelectric power dam and plant completed in 1930, 6 m. from Cordele, develops 19,200 h.p.

**Flint, Sir William Russell** (b. 1880). Scottish painter. Born in Edinburgh, April 4, 1880, he was educated at Daniel Stewart's College, and Royal Institution school of art there. He came to London in 1900, and was on the staff of The Illustrated London News, 1903-07. At his best as a water-colourist and etcher, he became widely known through his illustra-

tions to various limited editions, e.g. Chaucer, Homer, Malory, and Kingsley's The Heroes. Elected A.R.A., 1924, and R.A., 1933, he was president of the Royal Society of Painters in Water Colours from 1936. He was knighted in 1947. He is represented by works in the British and Victoria and Albert museums, Fitzwilliam museum, Cambridge, and in the British dominions and the U.S.A. A biography, More Than Shadows, by A. Palmer, appeared in 1943.

**Flint Implements.** Primitive tools and weapons of flint, which

Sir W. Russell Flint, Scottish painter

Four on a Beach, a typical water colour painting by Sir W. Russell Flint, R.A.

from its conchoidal fracture can be worked by flaking or chipping. The term popularly includes quartzite, chalcedony, felsite, chert, hornstone, and other siliceous stones. Perhaps originating in N. Africa, and traceable in a rudimentary form in the dawn of prehistoric Europe, they reached a high level of development during the Stone Age. When flint is broken up by percussion or pressure a conchoidal or shell-like fracture results, with a bulb of percussion where the blow falls. The products are classed as nodules, cores, flakes, chips, and splinters. Long exposure causes a characteristic tinting or patina.

Palaeolithic workshops—with anvil-stones, discarded cores, and spoiled implements—are plentiful, as at Crayford, Kent, and Caddington, Beds. The early Neolithic industry is revealed at Campigny and Grand Pressigny, France; later British factories are Grovehurst, Kent; Skelmuir, Aberdeenshire. Early flint mines have been localised at Spiennes, Belgium, Cissbury Hill, and Grime's Graves. Traces

Flint, Wales. Ruins of the castle built by Edward I

of the flint-knapping industry originally for gun-flints and strike-a-lights survive at Brandon, Suffolk. English flints are sometimes 9 ins. long; the finest, sometimes 14 ins. long, come from predynastic Egypt and from Denmark, with exquisite ripple-markings.

Implements of remote date are found in S. and W. Africa, Somaliland, Palestine, India, Burma, and America; their production survives in various parts of the world, e.g. in Australia. Pygmy flints,  $\frac{3}{8}$  in. to  $\frac{1}{2}$  in. long, traceable in the upper Palaeolithic age, became commoner in the Mesolithic Tardenoisian; they range from England (E. Lancashire and Scunthorpe) across Europe to Egypt (Helwan), and thence to India in the Vindhya hills. See Celt; Eolith; Neolith; Palaeolith; Tomahawk; also Anthropology and Aztec illus.

**Flint Lock.** Firing mechanism used on muskets before the introduction of percussion cap cartridges. The flint lock consists of a metal hammer engaged with a trip on the trigger; a flint fixed to the side of the lock; and a small flash pan containing the priming powder. The flint lock is cocked by pulling the hammer to the rear, where it is held by the trigger trip; when the trigger is pressed, the hammer flies forward and strikes the flint, causing a shower of sparks to fall in the flash pan and ignite the priming. The flash pan was usually provided with a cover

Flint Lock. Mechanism of firing device of a 17th century musket

to prevent the priming falling out and getting wet. In some types the cover was automatically raised from the flash pan when the lock was cocked. The flint lock was invented by the Portuguese about 1600, having been developed from the Japanese tinder box. In 1630 it was adopted in France, where it was called *fusil* from *fusile*, a flint. It was introduced into England in the reign of William III, and was the standard British infantry weapon until displaced by the percussion cap in 1840. Early flint locks fired one round every  $2\frac{1}{2}$  min., later types up to 12 rounds.

**Flintshire.** Northern maritime and the smallest co. of Wales. It lies to the W. of the Dee estuary, with a detached portion situated E. of Denbighshire; area, 256 sq. m. A hill range partly crosses the co. parallel to the Dee estuary, which at low tide is a sandy

Flintshire arms

waste. The co. contains the lower courses of the Dee and Clwyd; there are several valleys of considerable beauty, and in these the soil is fertile and under cultivation. Dairy and sheep farming also prosper. Coal, lead, iron, and other minerals are worked. There are iron and steel works along the Dee estuary; artificial silk and flannel are manufactured; and there are cement-making works.

Mold is the county town; Rhyl and Prestatyn are seaside resorts; Flint, Buckley, Connaught Quay, and Holywell are other towns. Flint and Rhuddlan have ruined castles, built by Edward I. In 1948 a second M.P. was allotted to the county, which is mostly in the diocese of St. Asaph. Pop. 112,889. Consult History of the Diocese of St. Asaph, D. R.

Thomas, 1908-13; Ancient Monuments in Wales and Monmouth, publ. Royal Commission, 1912.

**Flintshire Lead Process.** A reduction process which has been used from remote times in N. Wales. Pure ores obtained from limestone formations are used. The furnace is of the reverberatory type, having the hearth sloping to a central well, from the bottom of which a tap hole drains to a pot outside. A preliminary roasting of the charge on the hearth is followed by a raising of the temperature till the lead begins to run freely, then by a further rise to melt the charge down, the introduction of lime, stirring and mixing, a further roasting, draining, the introduction of a little coal slack to finish, and the tapping out of the metal. See Lead.

**Floating Battery.** The guns mounted on a ship or barge for bombarding shore positions from the sea. In the Second Great War floating batteries of rocket guns carried on special self-propelled barges were used to saturate the beach defences preparatory to the infantry landing in Normandy. See Rocket Weapons.

**Floating Debt.** Term used in national finance. The national debt of the U.K. may be classified into funded debt, not repayable on any definite date, and unfunded debt, repayable on a definite date. Of the unfunded debt, that part issued for a period of less than a year is called the floating debt. It consists of treasury bills, treasury deposit receipts, and ways and means advances. Treasury bills are usually for three months and are offered for tender periodically or sold continuously. T.D.R.s are for six months and now appear as one of the most important assets in the balance sheets of the big banks. Ways and means advances represent the current overdraft of the state. On March 31, 1946, the national debt was roughly £23,637 millions, of which the floating debt was £6,487 millions, made up of treasury bills, £4,423 millions; T.D.R.s, £1,559 millions; ways and means advances, £505 millions. See National Debt.

**Floating Island.** Floating mass of peaty vegetable materials, which collect in the shallower parts of the floor of a lake, and are probably buoyed up by the gases of their decomposition.

**Floating Kidney.** Condition in which the kidney is abnormally mobile and can be moved within the abdomen by manipulation.

Flintshire. Map of this Welsh county showing the detached portion between Cheshire and Shropshire

Lesser degrees of the condition are known as palpable kidney and movable kidney. Common causes of floating kidney are alterations in pressure due to loss of fat; repeated pregnancies; and a general sagging down of the viscera known as *enteroptosis*. Mild cases can be treated by suitable corseting and bandaging of the abdomen. Serious cases need surgical attention.

**Flocculi** (Lat. *floccus*, a lock of wool). Markings bright or dark on photographs of the sun taken in the light emitted by one kind of element, e.g. hydrogen. See Sun.

**Flock** (Lat. *floccus*, a lock of wool). Material used for stuffing beds, cushions, and upholstery, and consisting of either wool waste recovered during the finishing operations of milling, shearing, and raising woollen fabrics, or of the fibres produced by "breaking" worn woollen rags and waste yarn, i.e. tearing them into their constituent fibre by machinery. Flock is obviously liable to contamination with dirt and even infectious material.

Under the Rag Flock Act, 1911, amended 1928, flock from rags of old or new cloth must meet a standard of cleanliness prescribed by the ministry of Health. See Wool.

**Flock Book.** Register of sheep. Special societies, dealing with almost every variety of sheep, publish a flock book in which all pure-bred animals belonging to members are registered and the points of the breed laid down officially. See Sheep.

**Flodden, BATTLE OF.** Fought between the English and the Scots, Sept. 9, 1513. Flodden is a ridge of the Cheviots on the English side of the border. It is 3 m. S.E. of Coldstream, and nearer is the village of Branston. Along it runs the road to Scotland, and near is the Till, flowing to join the Tweed.

Suddenly renewing the war with England, James IV crossed the border on Aug. 22 with a large army and besieged Norham Castle, Surrey, charged with defence of the realm while Henry VIII was fighting in France, collected an army, and marched N., learning on the way that Norham and other castles had fallen to the invader. On Sept. 7 the two forces were only a few miles from each other. Surrey, by a circuitous march, placed his vanguard between the enemy and their line of retreat. The rest of the army moved on an interior line, and on the afternoon of the 9th, were ascending the ridge

whereon the Scots stood—but from the N., not from the S.

Seeing the enemy, James led his men down the ridge to meet them, and the battle was joined at once. Gradually the English gained the upper hand, and the Scots on the wings were soon in flight. On both sides the centre, picked soldiers under James and Surrey respectively, stood to fight it out. It was an unequal duel, for other bodies of English closed round the Scots, who were charged by horsemen from the rear, and when their king was killed they had decisively lost the battle.

The losses of the Scots have been placed at 11,000 out of 40,000 engaged, but both figures are too high. Certain it is that they lost heavily, especially among the nobles, who fought to the last around the king, and it is this that made the day so sad to Scottish memories. The English losses were perhaps 1,000. The best known reference in literature is Scott's description in *Marmion*. A monument, known as the King's stone, marks the spot where James is supposed to have been killed.

**Flogging.** Punishment for crime. In English law, flogging was abolished by the Criminal Justice Act, 1948, except as a prison punishment, and as such it can be awarded only in the case of mutiny, incitement to mutiny, or gross personal violence to a prison officer. Birching, a former punishment for boys under 16, was also abolished by the same Act.

**Flood.** Submersion of land by overflow of water. After extra heavy or prolonged rainfall, or in spring and summer, when snow and ice fields melt, great quantities of surface water drain directly into rivers. At the latter period floodwater is often held up by ice barriers in the lower reaches. The banks cannot contain all the water, which, overflowing, submerges the low-lying parts of the valley. Many parts of the world have clearly marked wet and dry seasons; heavy rains during the wet season cause floods, but the same rivers during the dry season are merely dry courses containing small lakes in the deepest parts of the bed. Floods may be caused by the effects of tide and wind, e.g. in the Thames and Elbe.

Egypt is aptly called "the Gift of the Nile," for in that land occurs the phenomenon of extensive floods in a land of little or no rainfall. The Nile rises in great lakes, situated in a region where rain falls at all seasons, thus

ensuring a steady current of water. But tributaries like the Sobat, Blue Nile, and Atbara have their sources in regions of heavy summer rainfall, and the summer water they bring down causes floods along the lower course of the main stream. But for these waters Egypt would be a desert.

The character of the soil may also aid floods. Large areas of N. England and Scotland are composed of hard or impervious rocks, from which the water is rapidly drained into the rivers, so that the latter are quickly in flood during heavy rains and very low during dry weather. Where limestone or other pervious rocks are found, rain sinks into the ground and the rivers maintain a steady flow, even in dry weather. The Mississippi basin and the great Chinese plains often experience disastrous floods. See Deluge.

**Flood, HENRY (1732-91).** Irish statesman and orator. Educated at Trinity College, Dublin, and

Henry Flood,  
Irish statesman  
After Comerford

Christ Church, Oxford, and called to the English bar in 1750, he entered the Irish house of commons in 1759 as member for Kilkenny. His closely reasoned oratory and his mastery of parliamentary tactics made him leader of the national party, and in 1775 he was made a privy councillor and vice-treasurer of Ireland. His opposition to Henry Grattan (q.v.), who superseded him as party leader about 1781, on the "simple repeal" question led to their famous quarrel, Flood urging the renunciation by England of all claims to influence Irish legislation. He remained loyal, however, to George II. In 1783 Flood was returned to the British house of commons as member for Winchester. He died Dec. 2, 1791.

**Floodlighting.** Effect produced by illuminating the exterior of buildings by powerful concealed electric lamps provided with suitable reflectors. Floodlights were originally used in theatres for special stage effects and later in film studios. For exteriors it was realized that floodlights at night shining upon the vertical faces of buildings of architectural note or historical interest could bring out beauties of design which daylight failed to reveal.

Floodlighting. The Royal Naval College at Greenwich, designed by Inigo Jones, John Webb, and Wren, reveals new architectural beauties when floodlit

White floodlighting is the most efficient form of illumination. Coloured floodlighting, using screens in the lamps, is spectacular but is relatively more costly. In some coloured floodlights in the light issues from a gaseous discharge tube, the colour is produced without screens by the characteristic properties of the gas with which the tube is filled. Floodlighting has been used for advertising with success, particularly for illuminating poster sites. The light is turned on and off by a time-switch. Floodlighting is also used in building so that construction can proceed after dark. During the Second Great War portable floodlights were used to facilitate rescue of people buried in bombed buildings. The fire services also provide small floodlights on their engines.

**Floor.** Horizontal division in a building. Floors are described according to position as ground floor, first floor, etc., intermediate levels being known as mezzanine floors. In houses they are usually constructed of timber bridging joists which rest on the walls. When the walls are widely spaced steel or timber beams are used to give intermediate support. Ground floors may be of concrete resting on the ground (solid floors) or of

joists supported on low brick sleeper walls, leaving a space under the floor which must be ventilated. In multi-storey buildings, which must be fire-resisting, concrete reinforced with steel rods is the most suitable material. There are many proprietary forms of floors, some entirely of reinforced concrete (pre-cast or cast *in situ*) and others with hollow tile blocks with reinforced concrete ribs between. Wood floors are finished with boarding, sometimes covered with a thin layer of hardwood laid to a pattern and known as parquet. Concrete floors can be finished with boarding, wood blocks, tiles, marble, etc.

**Floorcloth.** Type of floor covering made by building up successive layers of oil, chalk, and pigment on a woven backing and printing the surface. Such "oilcloth" is not much used nowadays. Kamptulicon (patented by Galloway in 1844) was made of rubber mixed with naphtha, gutta percha, and mineral fillers, but its development was discontinued about 1857 when rubber became too costly owing to vulcanisation. Linoleum (patented by Walton in 1861) is made of oxidised linseed oil, ground cork, gum, pigments, etc., on a woven canvas or other backing. Its simplest form, plain

linoleum, is used as a base for printed linoleums, in which the surface is printed with patterns. Variations of plain linoleums are jaspé, moiré, granite, sheet marble, effects obtained by variations in the mixing and calendering. In-laid linoleum (first produced 1880) is made by inlaying patterns of plain or multicoloured strips or granules on a canvas backing, the pattern going right through. Cork carpet is similar, except that coarser granules of cork are used and a smaller percentage of oxidised linseed oil, the result being a softer, more resilient surface. Felt base floor covering is made of bituminised paper felt with a printed surface.

**Floors OF FLEURS CASTLE.** Seat of the duke of Roxburgh. It stands on the Tweed just W. of Kelso. The Kers had long had a residence here when in 1718 Sir John Vanbrugh planned a new house for the duke of Roxburgh. In the middle of the 19th century it was largely rebuilt, being made into a magnificent building in the Tudor style. It has large gardens and commands extensive views. A holly tree is said to stand where James II was killed in 1460.

**Floquet, CHARLES THOMAS** (1828-96). French statesman. Born at St. Jean-Pied-de-Port, Basses Pyrénées, Oct. 2, 1828, he became an advocate and joined the Republican party. He was active in the overthrowing of Napoleon III, and sat as deputy for the Seine in the national assembly of 1871. Suspected of dealings with the communists, he was imprisoned by Thiers' government, but returned to the chamber as one of the deputies for Paris, 1876.

President of the chamber 1885-88, he became president of the council, and formed a radical ministry on April 3, 1888. On

Floor. Sectional view of a timber framed ground floor, showing how concrete is used in the construction of the hearth; the sleeper walls and piers and the position of the damp course are also seen

Flora Day. The famous Furry Dance being performed in the main street of Helston, Cornwall, on Flora or Furry Day, May 8

July 12 General Boulanger demanded a dissolution, and his accusations of falsehood against Floquet led to their fighting a duel next day, in which both were wounded. The ministry began to lose favour after bringing in a constitutional reform bill, and resigned Feb. 14, 1889. Re-elected president of the chamber, Floquet held this post until it was shown that he had received about £11,500 from the Panama company for the use of his party. This forced his resignation, Nov., 1892, though he made a full statement of defence at the trial of those more culpably involved. He died Jan. 18, 1896.

**Flora.** The collective species of plants growing naturally in any district or country, e.g. the flora of Wales. Also used for a book describing plants, arranged according to the laws of botanical classification.

**Flora.** In Roman mythology, the goddess of flowers. She had a temple near the Circus Maximus, and her festival, Floralia, was held every year from April 28 to May 1.

**Flora Day or FURRY DAY.** Holiday observed at Helston, Cornwall, on May 8, the feast of the apparition of S. Michael, patron saint of the town. Its origin was probably pre-Christian and connected with the pagan spring festival. The day was formerly given over to revelry, any person found working being made to leap the river. The Furry Dance is still performed through the streets and in and out of the houses, the dancers headed by a band. Another custom observed is the Halantow; men and boys go into the river valley collecting greenery, and then form a rowdy procession headed by a donkey, blowing mayhorns and singing through the streets a song concerning Robin Hood and Little John. Furry Day attracts crowds of

visitors. The song called The Floral Dance, composed by Katie Moss, refers to this celebration.

## FLORENCE: ITS HISTORY & TREASURES

Cecil Headlam, Author of *Venetia and Northern Italy*

*The city and its buildings are here described, and the history of the state that grew up around it is outlined. See Tuscany; Medici; and biographies of Savonarola, Macchiavelli, and other great Florentines; also Italy: History, Literature, Art; Guelphs and Ghibellines*

Florence, called by the Italians Firenze, lies on both banks of the Arno. The river was spanned,

Florence arms

before the Second Great War, by six bridges, and lined on the N. by modern quays (Lung'arno). Broad boulevards mark the line of the old walls on the right bank.

Across the river (Olt'arno) the walls and gateways begun by Arnolfo di Cambio, 1285, in succession to the smaller circuit of 1173, and still earlier Roman square, remained almost intact. Set in a valley among the foothills of the Apennines and the Monti di Chianti, Florence owes to the proximity of mountains and sea a variable and trying climate. To this may be ascribed in part the intellectual pre-eminence of her citizens.

The site and development of the city were determined by a natural crossing point in the Arno, where, narrowed by the hill of San Giorgio and deepened by the tributary Mugnone, its navigable course begins soon after it turns W. towards Pisa and the Tyrrhenian Sea. Here, at a point indicated by the recently destroyed Mercato Vecchio, or old forum, later the Piazza Vittorio Emanuele, and the picturesque Ponte Vecchio, designed by Taddeo Gaddi in 1365, the Roman road to the N. probably crossed an older Etruscan road

**Floréal.** Eighth month in the year as rearranged by the authors of the French Revolutionary calendar. It began on April 20 or 21, and the word means the month of flowers.

**Florence.** Province of Tuscany, N. Italy. It lies S. of Bologna, and N. of Siena and Arezzo, midway between the Adriatic and the Ligurian seas. The surface is hilly, and occupies part of the basin of the Arno. The soil is fertile, olives and grapes growing in profusion. Much wine is made, and silk is manufactured. Sheep are reared on the grassy uplands. The capital is Florence; other towns of importance are Prato, Empoli, Fiesole, and Figline. Pop., pre-war, 839,774.

running E. and W. Etruscan walls at Fiesole and Etruscan antiquities in the Museo Archeologico recall the original settlers.

Roman remains include a theatre at Fiesole, and in Florence, baths (Via delle Terme), and an amphitheatre (Piazza Peruzzi). A great temple of Mars is represented in its Christianised form by the baptistery of San Giovanni (Battistero), with its superb gilded doors by Pisano and Ghiberti. The Tuscan-Romanesque churches of S. Apostoli and San Miniato mark the rise of Florence in the 11th century. They inspired the Renaissance churches of Brunelleschi, San Spirito, and San Lorenzo. The latter, near the palace of the Medici, has always been closely connected with that family. Here, besides the domed mausoleum added by Cosimo I, is the new sacristy built by Michelangelo for Pope Clement VII (1524), where that artist's wonderful statues of Day and Night, Evening and Dawn, guard the monuments of Lorenzo and Giuliano de' Medici. Here, too, is the Biblioteca Laurenziana, the priceless library of books and manuscripts collected by Cosimo and Lorenzo il Magnifico, and housed by Michelangelo.

In the 13th century Florence became a veritable forest of towers, built by turbulent nobles, as in the Borgo Santissimi Apostoli. She was now to be adorned with vast Gothic churches and splendid public buildings, such as the palace of the Podestà, the Bargello,

which enshrines the National Museum, and the Palazzo Vecchio, with its soaring tower and projecting battlements, designed (1298) by Arnolfo di Cambio, for the safe housing of the Priori. The adjoining open-vaulted Loggia dei Priori (or Lanzi) was begun in 1376. The captain of the people resided at the Badia, a Benedictine Abbey founded by the mother of Count Hugo of Tuscany, whose graceful campanile dates from 1300.

The first great period of Florentine art coincided with the establishment of democratic government. Niccolò and Giovanni Pisano in sculpture, and in painting, Cimabue, his pupil Giotto, and Andrea Orcagna led the way in the great era of artistic freedom and grace, inspired by that same passionate interest in life as Dante and Boccaccio exhibit in verse and prose. In architecture, Arnolfo di Cambio, besides the city walls and the Palazzo Vecchio, built Santa Croce for the Franciscans (1297). Here, as in the building of the Duomo, he was succeeded by Giotto and Francesco Talenti. In 1420 the great dome of this, the fourth largest church in Europe, was begun by Filippo Brunelleschi. Giotto's lovely campanile, with its four storeys of marble, was begun, 1334, and completed by Andrea Pisano and Francesco Talenti, 1387.

#### Church Architecture

S. of the Piazza del Duomo is the graceful little Loggia del Bigallo (1352), resembling in style Andrea Orcagna's more gorgeous tabernacle in that splendid sanctuary of the guilds, Or San Michele, begun in 1337. The Dominican church of Santa Maria Novella was begun in 1278. The façade is by Leo Battista Alberti, the lovely arcade by Brunelleschi, and the exquisite Spanish chapel by Fra Jacopo Talenti. The much modernised church and convent of San Marco fascinates both by the art of Fra Angelico and Fra Bartolommeo, and its memories of Savonarola. The great 14th century church of the Santissima Annunziata has also been much altered, but contains some of the finest work of Andrea del Sarto.

The story of Florentine art, as it developed through Masolino and Masaccio, Fra Angelico, Lippi, Andrea del Castagno, to Andrea Verrocchio, Sandro Botticelli, Domenico Ghirlandaio and Leonardo da Vinci, Michelangelo Buonarroti and Raphael, and a host of other great artists, including Luca and Andrea della Robbia, Vasari, Benvenuto Cellini, and Gian di Bologna, can be followed in these and other churches, as well as in the great

galleries, the Academy of Fine Art, the Uffizi Palace, government offices constructed by Vasari for the grand duke Cosimo I, and the Pitti Palace. The latter, like the Palazzo Strozzi and Palazzo Rucellai (Alberti), is a typical Renaissance palace, and was begun by Luca Pitti, the opponent of Lorenzo the Magnificent, and afterwards occupied by his successors.

**HISTORY.** Florence was founded by the Etruscans. They had first settled at Fiesole, about 700 B.C., upon a rocky height to the N., commanding the way across the neighbouring Apennines to the Adriatic coast. Tempted down to the banks of the Arno by the commercial advantages of plain and river, they were presently supplanted by the Romans, whose quadrangular castrum is described as *municipium splendidissimum* in the time of Sulla.

Saved from the Goths by the legions of Stilicho and the prayers of Zenobius, a saintly bishop whose miracles often figure in Florentine art, the inhabitants fled later for refuge to Fiesole before the Lombards, but prosperity returned to their city under Charlemagne. The great power of the margraves of Tuscany delayed the rise of the Tuscan towns; but under the protection of Matilda, countess of Tuscany, and after her death in 1115, while Papacy and Empire were fighting for her heritage, Florence developed into a powerful, independent burgher city. Members of the chief families who had administered Florence in Matilda's name, now became consuls of the commune, annually elected, two for each *sestiere*, and were advised by a senate of 100 drawn mainly from the trade guilds. They led the burgher forces in their struggle against imperial vicars and feudal nobles. For the surrounding country, called the *contado*, bristled with castles, whence barons, of Teuton origin and adherents of the Empire, harried the pack-trains of the citizens.

#### Growth of the Commune

As the commune made herself mistress first of Fiesole (1125), and then of the *contado*, she compelled these barons to take up their residence within the city. There they joined with other citizen-nobles of aristocratic tendencies and fortified themselves in lofty towers. Against these societies of the towers, and the domination of an alien power, the burghers of the commune, a commercial democracy of Latin descent, grouped into trade guilds, strove unceasingly. This is the form which the feud betwixt

Guelph and Ghibelline took in Florence.

Her interest as a growing banking and carrying community on the trade-route from Rome naturally inclined Florence to the side of the Church, while involving her in commercial rivalry with Pisa, which barred her free communication with the sea; with Siena, the leading city between her and Rome; Pistoia, and other Ghibelline cities. For centuries she waged deadly trade wars with these rivals until she finally reduced them to subjection. The murder of one of the Buondelmonti, leaders of the democratic party, accentuated the bitterness of party faction.

Beneath the mask of family feuds, the Florentine commune was always striving, through successive changes in the constitution, and in spite of frequent reactions, towards the completest form of democratic liberty known to the Middle Ages. The lower class of artisans and the populace had as yet no share in the government (*Signoria*), except as a parliament (*Arengo*), assembled in the city square to shout a decision upon momentous matters. But the struggle between people and patrician magnates by this time had already begun.

#### Democratic Developments

The Guelph magnates remained in power, leading the Carroccio and red and white banner (*gonfalone*) of the commune to victory against their neighbours until, in 1249, the Uberti, aided by the Emperor's German troops, thrust them into exile. On the death of Frederick II in 1250, however, the people rose and established the first democratic constitution. Twelve elders (*anziani*) and thirty-six corporals (*caporali*) were appointed as a central government. A popular militia was formed, and a foreign Guelph noble, assisted by a special and a general council, was annually elected as "captain of the people" to champion their cause against the Podestà (1250).

This officer, also an annually elected foreign noble, had replaced the consuls about 1200, and became the representative of the Ghibelline aristocrats and of imperial claims. He, too, presided over two councils; so that there were now two political organizations, that of the nobles and that of the people, within the Republic. Ten years later the exiled Ghibellines, rallying at Siena, and reinforced by the German mercenaries of Manfred of Sicily, defeated the Guelphs at Montaperti.

The coming of Charles of Anjou, after the battle of Benevento, put an end to the domination of Ghibelline and German (1266). The

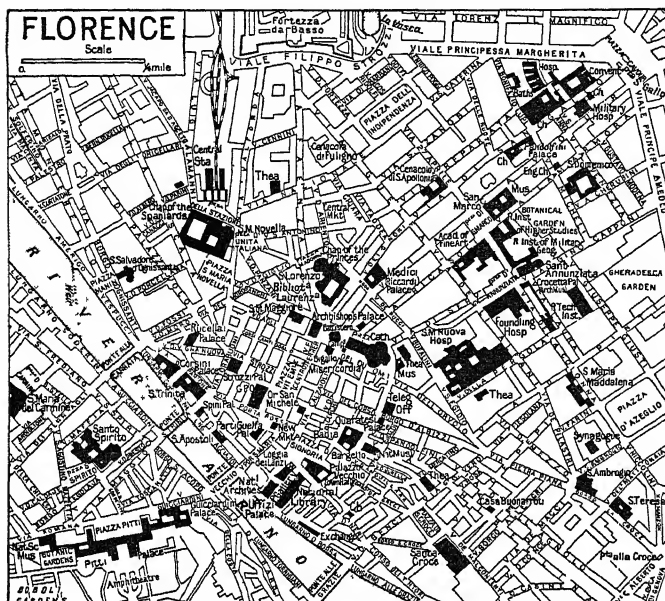

1. Palazzo Vecchio, 1298-1314, used as the town hall since 1871. 2. View from the church of S. Spirito, showing Giotto's campanile and dome of the cathedral. 3. Church of S. Croce, begun in 1294. The new façade built 1857-63. 4. Pitti Palace, begun in 1440, containing the famous picture gallery. 5. The Baptistery, c.1200. 6. Palazzo

Vecchio, the Renaissance courtyard built in the 16th century. 7. Cathedral of S. Maria del Fiore, crowned with Brunelleschi's dome, 1420-34. 8. Portico of the Uffizi Palace, 1560-74, containing Art Galleries and National Library. 9. Ponte Vecchio, across the Arno, built in 1345, and spared by the retreating Germans in 1944.

**FLORENCE: ITALIAN CITY FAMOUS IN LITERATURE AND ART**

Florence. Plan of the centre of the city, showing the principal buildings and bridges; most of the latter were demolished by the German army in 1944

Florentine Guelphs acknowledged Charles's suzerainty as king of Naples and Sicily. An organization (*Parte Guelfa*) was formed to persecute Ghibellines, and a new constitution (*Secondo Popolo*) similar to the first, but of a more democratic character, was set up.

In 1293 the famous ordinances of justice were enacted, intended to restrain the reviving power of the nobles, and barring them altogether from the *Signoria*. In 1300 a new officer of justice, the *Gonfaloniere*, or standard-bearer of the people, was added. Under this republic of merchants (*Villari*) the great "Trecento" era of art and literature blossomed forth.

#### Commercial Prosperity

The commercial prosperity of Florence was now great. Her merchants dealt in the wool of Latium and Lombardy, the oil and wine of Tuscany, the spices, silks, and dyes of the East; the craftsmen of the Calimala guild dressed and dyed foreign cloth into artistic fabrics, which were prized throughout Europe; while her bankers with their standard golden "florin," first coined 1252, provided the necessary medium of exchange, and extended her financial influence far and wide.

Head of the Guelphic League, Florence was now the chief power in Tuscany. At Campaldino (1289) she had shattered the remaining forces of the Tuscan Ghibellines. The Guelphs, however, soon split into factions, Neri

and Bianchi, headed by the Donati and Cerchi families. Dante, an adherent of the Bianchi, was banished when Charles of Valois, in alliance with the Neri, sacked the city, 1301. Nevertheless, the merchant republic succeeded in forming what was practically a confederation of all Italy.

The victorious Neri soon split into factions. Florence then fell a prey to the exactions of the Angevin sovereigns of Naples, and the tyranny of a French soldier of fortune, Walter de Brienne, duke of Athens. After his fall the people rose and annihilated the magnates, 1343.

#### Dawn of the Renaissance

The struggle for political power was henceforth between the rich burgher aristocracy (*Ottimati*) of the greater guilds and *popolo minuto*, the rest of the unfranchised guilds and people, typified by a rising of the latter (*Ciampi*), led by Michele di Lando, a patriotic wool-comber. The dawn of the Renaissance found Florence full of artists and scholars patronised by the Ottimati. Fierce wars were waged with Milan and other cities by mercenaries, such as those led by the English captain Hawkwood, and the dominion of Florence was extended over Pisa (1406), Arezzo, Cortona, and Leghorn. But the divisions of the Republic finally placed it at the mercy of Cosimo, son of Giovanni de' Medici, the richest banker in Italy. Returning from exile, he took his

place as Despot of Florence (1443). The outward forms of the old constitution were retained, while Cosimo controlled the elections and broke the power of the Ottimati. At home he patronised artists (Brunelleschi, Michelozzo, Donatello, Fra Lippo Lippi, Fra Angelico), and encouraged the Neo-Platonism of the Renaissance by his Platonic Academy. He was succeeded by his son Piero (1464) and his grandson Lorenzo il Magnifico.

#### Lorenzo and Savonarola

Lorenzo maintained the balance of power among the five Italian states, and was treated as an equal by foreign potentates. At home, Florence, beautified by artists sprung from the people, became the brilliant world-centre of the revival of Greek culture. But before Lorenzo's death Fra Girolamo Savonarola, denouncing the tyranny and corruption of state and church, had prepared the way for Republican reaction. Roused by Piero II's surrender to the French invaders, the people expelled the three sons of Lorenzo. Charles VIII entered the city, Nov. 17, 1494, and took the Republic under his protection. A brief period of political and spiritual reform, inspired by the prophetic fervour of Savonarola, was followed by the excommunication and burning of the monk (May 23, 1498).

The Gonfaloniere, Piero Soderini (1502), with Niccolò Macchiavelli for secretary of state, maintained the Republic until the Medici were restored by the Spanish invaders (1512). Republicanism made one last glorious effort under Niccolò Capponi (1527). But the emperor Charles V, in alliance with Pope Clement VII, who had ruled Florence as Cardinal Giulio de' Medici, reduced the town after a siege of eleven months.

Charles appointed Alessandro, illegitimate son of Lorenzo, son of Piero II, duke of Florence. Alessandro suppressed the ancient Signoria for ever. He was murdered in the Palazzo Medici by his kinsman, Lorenzino, and was succeeded by Cosimo I de' Medici, "the Great" (1537). Allying himself with Spain and the Papacy, and making himself master of the surrounding country, while he patronised the artists of the late Renaissance, Cosimo founded a long line of grand dukes of Tuscany (1569).

Florence remained the capital of Tuscany when, in 1737, the Medici line having become extinct, the duchy was annexed by the emperor and became an appanage of the House of Austria. After the Napoleonic interludes of the republic and kingdom of

Etruria, 1801-07, Tuscany joined the growing kingdom of Italy by a plebiscite in 1860, and Florence became the first capital of the united kingdom of Italy (1865-71).

Florence was declared an open city on July 1, 1944, during the fighting in the Second Great War, and by Aug. 5 the suburbs on the S. bank of the Arno were in Allied hands. The Germans had destroyed all the bridges except the Ponte Vecchio, and did not evacuate the city until Aug. 11. They shelled it on Aug. 20, causing many casualties among civilians returning from church. British troops entered next day, when fighting between the fascists and Italian patriots had ceased. The Germans had removed works of art from the city galleries, some to villas surrounding the city, where they were found by the advancing allies, others to salt mines in Tirol, where they were discovered after the German surrender. All were accounted for and returned to Florence by July, 1945. The pre-war pop. of the city was 322,535.

Standard histories of Florence are by H. E. Napier, 6 vols., 1846-47; T. A. Trollope, 4 vols., 1865; G. Capponi, 2 vols., 1875 (in Italian); F. T. Perrens, 9 vols., 1877-90 (in French, Eng. trans. H. Lynch, 1892). Consult also A Wanderer in Florence, E. V. Lucas, 1912.

**Florence of Worcester** (d. 1118). English chronicler. A monk at Worcester, he lived in the time of William I and Henry I and died in July, 1118. His chronicle of English history begins with the Creation, and is filled with stories and legends from earlier writings, but is valuable for the period covered by the author's life. The work was continued to 1141 by John of Worcester. An Eng. trans. was edited by B. Thorpe, 1848.

**Flores.** Island of the Azores, in the Atlantic Ocean. It is the most westerly of the group. The surface is mountainous, and sheep are reared on the grassy slopes. The soil is fertile, and fruit and vegetables are cultivated. The chief town is Santa Cruz. Off Flores, in 1591, took place the naval action between Sir Richard Grenville in the *Revenge* and several Spanish vessels, described in Tennyson's poem.

**Flores.** Island of East Indonesia, in the Sunda group of the Malay Archipelago. A dependency of Timor, it lies S. of Celebes, from which it is separated by the Flores Sea, midway be-

tween Java and Timor. Oblong in shape, it is 230 m. from W. to E., with an average breadth from N. to S. of 28 m., and an area of 5,860 sq. m. The chief products include sandalwood, cotton, edible birds'-nests, dyewoods, tortoiseshell, and beeswax, while rubber culture is making progress. Pop. approx. 250,000.

**Flores.** Department of S.W. Uruguay. It is bounded on the N. by Durazno and on the S. by San José. It is hilly, with good pasture; agriculture and stock-raising are the principal industries. The capital is Trinidad, connected by branch line to Durazno on the rly. running N. from Montevideo. Area 1,744 sq. m. Pop. 36,125.

**Flores Sea.** Part of the S. Pacific Ocean. It lies between the island of Flores on the S. and Celebes on the N., E. of the Sunda Sea and W. of the Banda Sea. There are many islands and coral atolls in this sea.

**Floret** (Fr. *fleurlette*, little flower). Term used to denote a small flower, one of a number closely packed together, presenting in the aggregate the appearance of one large flower. This especially applies to the large family Compositae. In the common daisy (*Bellis perennis*) what is popularly called the flower is a closely packed head (*capitulum*) of about 250 florets, of which four-fifths are short, yellow-coloured tubes, constituting the disk. Around the disk is an outer series in which the tube has been split into a much larger white strap. These ray-florets contain no stamens; their principal purpose is to make the flower-head conspicuous and attract insects to effect cross-pollination. Groundsel (*Senecio vulgaris*) has all its florets without rays, while in dandelion (*Taraxacum officinale*) they are all rayed.

**Floreys, Sir HOWARD WALTER** (b. 1898). Australian pathologist. Born Sept. 24, 1898, he was educated at Adelaide university, and Magdalen College, Oxford. Professor of pathology at Sheffield, 1931-35, he later carried out experiments and research on penicillin at the Oxford school of pathology. Among his team of collaborators was E. B. Chain (q.v.). Although the initial discovery of penicillin was due to Sir Alexander Fleming (q.v.), Florey's work from 1938 led to the separation of the drug later used in medical treatment from the original penicillin which contained poisonous substances. He was knighted in 1944; in 1945 he

shared the Nobel prize for chemistry with Fleming and Chain; in 1946 he received the Albert gold medal from the Royal Society of Arts. See Penicillin.

**Florian, JEAN PIERRE CLARIS DE** (1755-94). French author and academician. Born March 6, 1755, he obtained an appointment in the household of the duke of Penhièvre, and afterwards held a commission in a cavalry regiment. He was imprisoned when the Revolution broke out, and died Sept. 13, 1794, soon after his release. Author of several comedies, romances, and pastorals, he was elected to the French Academy in 1788. He is remembered chiefly for his Fables, 1792.

**Florianopolis.** Seaport and city of Brazil; capital of the state of Santa Catherina. Its old name was Desterro. It stands on the W. coast of Santa Catherina Island, 260 m. S.W. of Santos, and is connected to the mainland by a steel bridge 935 yds. long. The fine harbour is guarded by forts. There are a cathedral, government palace, arsenal, hospital, high school, etc. Dairy produce, maize, rice, and tobacco are exported. Pop. 47,150.

**Florida.** State in the extreme S.E. of the U.S.A. Bounded N. by Alabama and Georgia, its area is 58,560 sq. m., including 4,298 sq. m. of inland water, almost exactly the size of England and Wales. It is designated the Peninsular State from its peculiar elongation, or the Everglades State because of 4,472 sq. m. of overgrown marshland in the extreme S. Its tidal coastline, the longest of any state, measures 3,751 m., including the Ten Thousand Islands off the W. coast.

Of limestone formation, Florida has 30,000 lakes, including Okeechobee, 717 sq. m., in the Everglades; many navigable rivers, including the St. John's, Suwannee, and Apalachicola, and innumerable subterranean streams; but no mountains and little elevation. The state passes through three climatic zones, from warm temperate in the N. through semi-tropical to sub-tropical in the extreme S., where a daily average of over 6 hours' sunshine and a mean temp. of 69° F. allows four distinct growing seasons. This portion, which benefits from the Gulf Stream and trade winds, does occasionally suffer from West Indian hurricanes. Frost is unknown at Key West, 100 m. off the mainland. Florida has 3,000 varieties of indigenous flowering

plants, half the tree species found N. of Mexico, and hundreds of species and sub-species of bird, butterfly, and fish.

Famous for oranges and other citrus fruits, Florida also grows pineapples, bananas, avocados, olives, figs, coconuts, peanuts, cotton, tobacco, maize, oats, and sugar cane. It yields 70 p.c. of the nation's phosphate, also fuller's earth, limestone, lime, cement, clay, and forest products. Sponge fishing is profitable. Cattle raising and tung-oil production are comparatively new industries. The pop. increased by 29 p.c. between 1930 and 1940, because of tourists becoming residents, the influx of new industries, and the establishment of military and naval installations, airfields, seaplane and submarine bases. It reached 1,897,414, of whom 514,198 are negroes.

Two senators and six representatives are sent to congress. Tallahassee is the capital. Educational institutions include the university of Florida at Gainesville, a state college for women, state agricultural and mechanical college (for negroes), and the universities of Miami and Tampa, which are privately endowed. St. Augustine, founded in 1565, is the oldest permanent white settlement in the U.S.A. Florida has 7,500 m. of rly., 45,000 m. of paved roads, and a canal system (not yet completed) which, with natural waterways, crosses the Everglades from the Atlantic to the Gulf. The longest overseas thoroughfare in the world, 131 m., over an abandoned rly. and bridges, connects the mainland with Key West, the southernmost city of the U.S.A.

Florida derived its name from the day in 1513 on which it was discovered by Ponce de Léon—Easter Day (Spanish *Pascua Florida* or Feast of Flowers)—and was by turns in the possession of Spain, France, and Great Britain till 1819. The state was admitted to the union in 1845 after having been a territory since 1822. *Consult* The Story of Florida, W. T. Cash, 1938.

**Florida.** Central dept. of Uruguay, bounded N. by Durazno and S. by Canelones. The surface consists of undulating grassy tracts, watered by the Yi river, upon which are reared vast herds of cattle. Area, 4,673 sq. m. Pop. 106,495. The capital is Florida, the centre of a trade in grain, 70 m. by rly. N. of Montevideo.

**Florida Bay.** Arm of the Gulf of Mexico. It separates Florida state, U.S.A., from Florida Keys.

**Florida Keys.** Curved chain of coral and limestone reefs off the S. coast of Florida, U.S.A. Extending S.W. for 175 m. from Miami, they include Key Largo, 30 m. long, and Key West, 4 m. by 2 m. only, but containing the southernmost city of the U.S.A. They are connected by highway with the mainland. Sponge fishing and catering for tourists are the occupations. *See* Key West.

**Florida Straits or CHANNEL.** Coastal waters off Florida, U.S.A., alternatively known as the New Bahama Channel. They separate the S.E. extremity of Florida and the Florida Keys from Cuba and the Bahama Islands. The channel is some 300 m. long, has a mean breadth of 80 m., and a greatest depth of 6,000 ft. It is traversed by the Gulf Stream.

**Florideae or RHODOPHYCEAE.** Class of Algae or seaweeds. In them the chlorophyll, or green colouring matter, is masked by a red pigment (phyco-erythrin). They have no true roots, but are attached to their supports by suckers, the absorbent function of roots being carried on by the surface cells of the entire plant.

**Florin.** Name of several gold and silver coins of various European currencies. A gold coin struck at Florence in 1252 bore, obverse, the figure of S. John Baptist, reverse, the Florentine lily, whence came the name florin (Ital. *florino*, little flower). Similar pieces appeared in various parts of Italy. Gold florins were also minted by Charles I of Anjou, c. 1335, and by John of Luxembourg, c. 1340. The English gold florin, of approximate value six shillings, issued by Edward III in 1343, was withdrawn in 1344.

The British silver florin, value two shillings, weighed 174.55 grains. It was issued in 1849, intended as

the first step in providing a decimal currency. A bill to bring this about was lost, but the florin continued to be minted. It was at first dubbed the "graceless florin," as the customary D.G. (*Dei Gratia*) did not appear on the issues between 1849–1852. The life of a florin in circulation is estimated at about 45 years.

**Florina.** A town of Greece, in Macedonia, formerly in Turkey-in-Europe. It is about 15 m. S. of Monastir (Bitolj), and was in the tract of territory acquired by Greece as a result of the Balkan wars, 1912–13. It came into prominence during the First Great War. Captured by the French, in April, 1916, it was retaken by the Bulgarians, Aug. 20, and then by Franco-Russian troops, Sept. 18. (*See* Salonica, Expedition to; Serbia, Conquest of.)

The town was overrun by the Germans in the early days of April, 1941 (*see* Greece, Campaign of 1941), and remained in Axis occupation until Nov., 1944. Pop. 10,585. Florina gives its name to a dept. with pop. 152,809.

**Florio, JOHN** (c. 1553–1625).

Author and translator. Born in London, he was the son of an

John Florio, translator of Montaigne

Italian Protestant who became minister to an English congregation of Italians who shared his religious opinions. John was educated at Magdalen College, Oxford, became a teacher of French and Italian in the university, and held various offices at court, including that of tutor to Prince Henry, son of James I. In 1598 appeared his Italian-English dictionary, *A World of Words*, and in 1603 his famous translation of Montaigne's *Essays*, on which his reputation rests. Florio died of the plague at Fulham. Ben Jonson was one of his friends.

**Florizel.** Character in Shakespeare's *The Winter's Tale*. He is the son of Polixenes, king of Bohemia, and falls in love with Perdita, who, brought up by a Bohemian shepherd, is the lost daughter of Leontes, king of Sicily. The name was applied to the Prince Regent (George IV) on his amour with the actress "Perdita" (Mary) Robinson, whom he first saw playing in *The Winter's Tale*. Prince Florizel is the chief character in Stevenson's *New Arabian Nights*

Florin. Gold coin of Edward III; top, florin minted in 1449

Actual diameter of Edward III florin, 1 1/4 ins.; of George VI florin, 1 1/2 ins.

**Florodora.** Musical comedy written by Owen Hall (James Davis) and composed by Leslie Stuart. It was produced Nov. 11, 1899, at the Lyric Theatre, London, where it ran for 455 continuous performances. Its most popular feature was the sextet, Tell me, pretty maiden.

**Floscularia**, OR FLOWER ANIMALCULE. Group of rotifers, common in most ponds. The body is supported on a slender stalk contained in a gelatinous tube, and the wheel-disk is provided with long, bristle-like processes which serve to entangle the minute particles on which the animal feeds. It is just visible to the naked eye.

**Flotation.** Method of mineral dressing, used in concentrating the valuable portion of ores or in removing unwanted constituents. It makes use of the fact that mineral particles may, depending on their type of surface, be made to stick either to water in which they are, suspended or to air bubbles formed in the water. A pulp may be agitated so that a froth is formed, which rises to the surface, carrying certain mineral particles up with it and leaving others in the pulp. Sulphides are particularly amenable to flotation.

The physical and chemical theory behind flotation is complicated. Most, possibly all, minerals can be made to adhere either to water or to air; organic and inorganic chemicals are employed to attain the right conditions. Chemicals which cause particles to stick to air bubbles are known as collectors; organic acids or their alkali salts, such as soaps or xanthates, oleic or palmitic acids, are examples. Typical controllers are alkali hydroxides, carbonates, and silicates, which act as "depressants," keeping certain particles in the pulp, while "activators," such as copper sulphate, alter the surfaces of minerals to help them respond to the collector.

Preparation of the ore by crushing, grinding, preliminary concentration by gravity methods, etc., is needed before an ore may be floated. The machines used differ in design. Usually the pulp is stirred mechanically by a paddle, while air is introduced down the shaft or the air is pumped through the flotation cell in such a way that it causes the necessary agitation. The froth flows over into a launder and forms the concentrate, while the pulp is drained off as tailings. Ores of most base metals and of gold may be

concentrated by the method, while coals may be purified. See Ore Dressing.

**Flotilla** (Span., small fleet). Tactical unit of a fleet consisting of a number of small naval vessels, such as destroyers, submarines, motor torpedo-boats, and minesweepers, grouped under a commodore or a captain and intended to operate as a single unit. The strength of a destroyer flotilla varies according to operational demands, but never exceeds 20 ships, exclusive of the flotilla leader, and is divided into two or more divisions. Although organized in flotillas, submarines usually work independently; during the Second Great War, however, submarine flotillas, often referred to as U-boat packs, were sent by the Germans against Allied shipping in the N. Atlantic. See Navy.

**Flotilla Leader.** A large destroyer accommodating the officer in command of a destroyer flotilla. The average flotilla leader in the Royal Navy displaces 1,870 tons on a length of 350 ft. and a beam of 36 ft. Engines of 44,000 s.h.p. give a speed of 36.5 knots. Armament consists of six 4.7-in. guns mounted in three turrets, 10 A.A. guns ranging in calibre from 4 ins. to 20 mm., and four 21-in. torpedo tubes. A flotilla leader carries a complement of 220.

**Flotow, FRIEDRICH, BARON VON** (1812-83). German composer. Of a noble family of Mecklenburg-Schwerin, he was born April 27, 1812, and studied music in Paris. Of his 18 operas the earliest, *Le Naufrage de la Méduse*, brought him a reputation there in 1839. *Stradella*, 1844, had great success in Germany but failed in England. *Martha*, first performed at Vienna 1847 and London 1849, is reckoned his finest work. The only other opera to attain popularity was *L'Ombre*, 1870. Flotow was intendant of the Court theatre at Schwerin 1856-63, and in 1864 was elected to the Institut de France. He died at Darmstadt Jan. 24, 1883.

**Flotsam and Jetsam** (low Lat. *flottare*, to float; Lat. *jactare*, to cast). English legal term. Flotsam is goods found floating on the sea, and jetsam means goods jettisoned, cast overboard in a storm, or washed on shore after a wreck. They become crown property unless claimed by the rightful owners.

This name was adopted in 1926 by a pair of music hall and radio entertainers; Flotsam being

Bentley Collingwood Hilliam, who played the piano and wrote all their songs, and Jetsam, Malcolm McEachern (d. 1945), Australian bass singer.

**Flounder** (*Platichthys flesus*). Small species of flatfish, common in the sea and the lower reaches of

Flounder, a small flatfish found round the coasts of the British Isles

ivers. It belongs to the same group as the plaice, but is smaller, seldom 12 ins. long. It has dark mottlings, and lacks the orange-coloured spots of the larger fish. The flounder produces from one to two million eggs. Its flesh is delicate, but its small size makes it unimportant as a food fish.

**Flour.** The finely ground endosperm of cereal grains, particularly wheat, which may also contain fractions of the protective skins and embryo (germ), according to the method of milling and degree of extraction obtained. When a definite proportion of bran layers is milled into wheaten flour, the product is wheatmeal, whereas wholemeal is ground from whole grain. Rye is also a bread grain, and to a lesser extent barley, oats, rice, and maize; a product from the latter cereal is known as cornflour. Flour is also obtained from farinaceous grasses, fruits, nuts, pulses, roots, and tubers; e.g. bananas, soya beans, potatoes, arrowroot, buckwheat, millet, cassava, manioc, and sago palm pith. Malted flour is milled from malted grain.

The term is also used to denote other finely ground products of commerce; two mineral supplements used in animal feeds are limestone flour and steamed bone flour. A further product is wood flour, obtained from sawdust and used in making plastics and in other industries.

The wheat grain, most important of the cereals used for flour in the W. hemisphere, is a seed, comprising pericarp and seed proper. The pericarp has three skin layers, whilst the seed is further protected by three inner coats, all of which comprise the bran separated in milling. Apart from its coats the seed contains the embryo or germ, situated dorsally at one end

Flour. Longitudinal section of a grain of wheat

of the grain and separated by its scutellar tissue from the endosperm, the main constituent. The first of the inner seeds coatings is the testa or colour-bearing layer, whilst the innermost layer is the aleurone, rich in mineral constituents and nutritive factors.

Grain components vary in proportion according to wheat type, but average figures are pericarp 4 p.c.; testa and hyaline layer 2.5 p.c.; aleurone layer 6-7 p.c.; germ 2.5 p.c.; endosperm 85 p.c. Typical average composition of whole wheat grain and its components is as follows, the four

sets of figures relating to (1) whole grain, (2) endosperm, (3) bran, and (4) germ.

	(1)	(2)	(3)	(4)
Moisture	12.2	13.8	12.5	13.5
Oil	1.8	1.2	4.7	10.8
Protein	13.2	12.0	15.0	25.9
Fibre	2.1	0.2	7.9	1.9
Ash	1.7	0.55	4.65	4.1

The principal proteins are glutenin and gliadin, which together with water form gluten, the elastic substance in the flour which traps the aerating gas generated in the bread dough and thereby forms the cell-like structure and framework of the loaf, holding together the starch and other components.

Dividing white flour into grades according to colour and quality is normal practice. When only one grade is milled it is known as straight run flour. White flour is usually milled at 70-72 p.c. extraction, but flours up to 80 p.c. extraction can be milled which are near-white in colour and possess similar baking characteristics to those of white flour but a higher

proportion of valuable grain nutrients. Flour milled at still higher extractions assumes the character of wheatmeal.

Nutritional items occurring in wheat are iron and calcium, although the availability of the latter decreases with higher extractions on account of the phytic acid present. Also there are the Vitamins B<sub>1</sub>, riboflavin, and nicotinic acid. The scutellum fraction of the germ is the richest source

Flour Mill. Separator for removing impurities such as straw, dust, etc., from wheat and other grain before milling  
*Courtesy of Thos. Robinson & Son, Ltd., Rochdale*

of Vitamin B<sub>1</sub>. Semolina is a flour mill product, used in making macaroni and vermicelli. Industrially, granular flour is used in the preparation of powder alcohol. The average gross imports of wheat and flour into the U.K. for the five years up to 1938-39 were 5,148,855 tons and 409,000 tons respectively. At the end of the Second Great War the average weekly consumption of flour in the country was about 100,000 tons, requiring 112,000 tons of wheat. The wartime loaf included roughly 75 p.c. imported wheat and flour—shipped from Canada.

**Flourens, GUSTAVE** (1838-71). French politician. The son of the physiologist, Marie J. P. Flourens (1794-1867), known as the associate of Cuvier, he was born in Paris, Aug. 4, 1838. He began life as a lecturer and writer, but was soon associating with revolutionaries in Italy and elsewhere. In Feb., 1870, he headed a futile rising against Napoleon III, and after the abdication of the emperor he was one of the leaders of the commune. He was killed during the fighting at Rueil, April 3, 1871.

**Flour Mill.** Building equipped for grinding grain, especially wheat, into flour. The application of steam power to millstone grinding in 1784 led not only to improved

Flour Mill. Longitudinal section of the milling separator shown in the photograph above. The flow of grain and the air currents are indicated

methods of direct reduction, but also to the invention of systems for gradual reduction by means of rolls. Millstones are still used for whole wheatmeal, oatmeal, and other grain and pulses. The stones—French burrs, Derbyshire peaks, or composition disks—are usually 1 ft. thick and 4-4½ ft. in diameter, scored with straight furrows tapering to ¼ in. in depth. The upper stones rotate at a maximum of 150 r.p.m.

Although small hand-turned roller mills were produced casually from the 16th century, it was not until 1837 that Sulzberger, a Swiss engineer, founded the modern iron roller system. Porcelain rolls, introduced in 1870, have now long been discarded. Roller mills were erected in Glasgow in 1872 and in Dublin in 1878. For some years stones and rolls were employed in the same mills. But after 1881, when an exhibition was held in Islington, British millers rapidly adopted the roller system, which today deals with all but a minute fraction of the flour milling of the world.

Roller mills are equipped with silos or granaries, containing storage bins of wood, steel, or ferro-concrete, and are filled from the intake plant consisting of bucket type elevator or pneumatic conveyors that can be lowered into ship holds, and deliver the grain on to horizontal screw or hand conveyors over the bins. Road or rail wagons discharge grain into silo wall hoppers. The grain is drawn from the bins for cleaning, which is effected by milling separators using a system of sieves and air currents. Magnets retain stray iron objects such as nails, and the grain is next subjected to scouring to loosen remaining husks and surface dirt. Cockle and barley cylinders follow; these have indents shaped so as to catch smaller and reject larger seeds respectively. Most grain requires washing; and wheat is next dried or mellowed to bring it into the best physical state for milling.

A roller mill stand contains two pairs of chilled iron rolls set diagonally and rotating at differential speeds. Break rolls are corrugated spirally with saw-tooth

Flour Mill. Sectional drawing showing the construction of the diagonal roller mill

grooving, ranging from 10-26 per inch. The rolls may be 9 or 10 ins. in diameter, and 15 to 60 ins. long, the speed of the fast or cutting roll being 350 r.p.m., the bottom holding roll rotating 2½ times as slowly. There are usually four or five break roll passages with a sieving process between each to pass the released endosperm particles into the remaining milling processes, where they are graded according to size into

whole process from raw grain to flour sack is automatic.

**Flow.** Term used in metallurgy to describe the effects of certain types of deformation on metals. When a metal is submitted to stress, it first deforms elastically, but once the elastic limit has been exceeded plastic flow takes place and the metal becomes permanently distorted. Although this seems similar to the flow of water, there is no question of liquefaction of the metal, as flow takes place at temperatures far below the melting point and is really analogous to the flow of ice in a glacier. One well-known example from ancient times is the movement or creep of lead down roofs of cathedrals and churches.

A metal is built up of crystals and each crystal is composed of a group of atoms in a regular pattern; in many metals the pattern is cubic. If a series of such adjoining cubes be considered, the atoms seem to be arranged on crystallographic planes, along which shear or gliding or slipping might be expected to take place more readily than along planes with atoms irregularly spaced. In fact slipping takes place on certain planes so that the metal moves in "blocks"; this block movement forms steps on a polished metal surface, which may be seen under a microscope as straight lines. In a normal metal of many crystals, slip starts in only a few; this movement redistributes the stress and other crystals become affected. Eventually the grain boundaries change in shape and the crystals become elongated in the direction of flow, giving a characteristic "flow structure," with all the long,

Flour Mill. Diagonal roller mill containing two pairs of chilled iron rolls rotating at differential speeds  
Courtesy of Thos. Robinson & Son, Ltd., Rochdale

semolina, middlings, and dunst. These granular stocks are purified by a combination of sieves and air currents which plant light particles of bran fragments over the sieves. The sieves grade the purified stocks to the various smooth reduction rolls, which have a differential speed 5 : 4, the top fast roll being driven at 250 r.p.m. They reduce the granular stocks into flour in successive stages and also flatten any germ or bran particles present. Where it is desired to mill the germ into the flour, finely fluted rolls are used on certain passages. The

fibrous crystals packed parallel to each other. The mechanism is not yet clearly explained.

Plastic flow takes place more easily at elevated temperatures, though still well below the melting point of the metal. In industry metals are caused to flow by such processes as forging, drawing, extrusion, and rolling. These processes may be carried out either hot or cold. *See* Annealing; Deformation; Elasticity.

**Flower** (Lat. *flos*, stem, *flor*-, flower). Part of a plant containing the organs of reproduction. In the complete flower it consists of four distinct whorls of organs, which differ in form and number in different species; one or more of the sets of organs being sometimes absent. The lower or outer set are the calyx-leaves, which form the bud of the unopened flower; separately they are known as sepals, and are usually green. The second series are corolla-leaves, mostly brightly coloured, separately known as petals. The third series are stamens, consisting of a stalk or filament and the anthers, the latter containing pollen—the male cells. The fourth series is the pistil, which consists of the ovary, containing ovules or seed-eggs, surmounted by a stigma or stigmas which may be supported by stalks or styles. Grains of pollen caught by the sticky or rough surface of the stigma send out tubes which penetrate the style and fertilise the ovules, which then develop into fertile seeds.

Sometimes the sepals are all joined together and can only be spoken of as the calyx. Similarly, the petals may be united to form a tube, and be funnel-shaped, bell-shaped, urn-shaped, etc. Where there is no distinction between sepals and petals (as in the crocus and daffodil) the floral envelope is termed the perianth. In the Gymnosperms (Conifers) there are neither sepals or petals; and in other forest trees these organs are often very small and inconspicuous, because the pollen is carried by the wind. As a general rule, where the petals are brightly coloured the pollinating agents are insects—mainly bees, butterflies, and moths. Each particular type of flower has its own group of pollinating insects.

In the majority of such specialised flowers nectar-producing glands are so placed as to make certain the transfer of pollen from one flower to the stigma of another by insect agency. So also the streaks, or lines of dots, of a

second colour on the petals point to the position of the nectar. The long tubes of certain flowers (tobacco, convolvulus, etc.) are related to the long probosces of the larger moths and butterflies; broad, open flowers like buttercups to beetles, etc. The perfume emanating from flowers attracts insects—bees, butterflies, and moths. On the other hand, some flowers, such as those of the stapelias, arum family, etc., emit fetid odours attractive only to flies, which are their pollinating agents.

**Flower, Sir** (WALTER) NEWMAN (b. 1879). British publisher and man of letters. Born at Fontmell Magna, Dorset, July 8, 1879, he was educated at Whitgift School, and joined the publishing firm of Cassell's in 1906, later becoming director, a position he resigned in 1946. Known for his monographs on composers, e.g. Sullivan, 1927, Schubert, 1928, he possessed a fine collection of books, MSS., etc., relating to Handel, his biography of that composer appearing in 1923. Flower, who was knighted in 1938, also edited the journals of Arnold Bennett, published in 3 vols., 1932–33.

Flowering Rush. Foliage, buds, and flowers of *Butomus umbellatus*

**Flowering Rush** (*Butomus umbellatus*). Perennial marsh herb of the family Alismaceae. A native of Europe and Asia, it has a stout, creeping rootstock, from which the slender leaves rise erectly to a height of 3 ft. or 4 ft. The tall flower-scape is leafless, and bears at its summit an umbel of many rose-red flowers, each 1 in. across, of which only a few open at one time.

**Flower of Jove** (*Lychnis flo-jovii*). Perennial herb of the family Caryophyllaceae. A native of Europe, it is covered with white, silky hairs, and has lance-shaped, stem-clasping leaves in pairs. Each branch of the stems ends in a small cluster of purple or scarlet flowers of the campion (*q.v.*) type.

**Flowers, LANGUAGE OF.** Custom said to derive from the East, by which a particular sentiment is attributed to every flower, so that a bloom or posy may convey a message. Little volumes in which the language of flowers was set out were popular in England in the mid-part of the 19th century. Gorse, for example, indicates enduring affection; jonquil, reciprocated affection; eglantine, I wound to heal, etc.

**Flower Show.** Horticultural exhibition, held for the purpose of encouraging the cultivation of plants, flowers, fruit, and vegetables. Exhibits may be competitive or non-competitive. The Royal Horticultural Society holds shows at fortnightly intervals throughout the year at Westminster. Local societies exist in most towns and many villages, annual shows being held, usually in Aug. or Sept. Hundreds of allotment associations also hold annual shows. In general the regulations for a flower show in the U.K. should be those laid down in the R.H.S. publication, Rules for Judging, but it may be advisable to require a smaller number of specimens than that specified for London shows. The schedule committee should avoid ambiguity in the wording of the classes, and use the expressions "kind" and "variety" correctly. The conditions under which challenge trophies are to be awarded should be clearly defined.

In selecting produce for exhibition the size of fruit and vegetables should be that which is best for table use. Beyond a certain point, size may become a defect. Only one variety should be shown in a dish or vase, unless a mixture is specifically asked for. Uniformity of specimens composing a dish is regarded as meritorious; unevenness in size or colour is a fault. With fruits the natural bloom should be preserved, and polishing of, e.g., apples should tell against an exhibit. All vegetables should be perfectly clean, but root vegetables should be washed carefully. The use of oil to produce an appearance of freshness should be regarded as a fault. All produce should be labelled with the varietal name, as information enhances the educational value of a show.

The most important flower show in the U.K. is the annual exhibition held in May in the grounds of the Royal Hospital, Chelsea, and known throughout the world as Chelsea Flower Show. There nearly all the exhibits are non-

Regular wild rose

Salver-shaped primrose

Rotate or wheel-shaped periwinkle

Campanulate or bell-shaped harebell

competitive, and include not only large groups of plants, flowers, fruit, and vegetables, staged in huge marquees, but also rock and formal gardens constructed in the open, and displays of every conceivable horticultural requisite, from a flower vase to a conservatory and from a budding knife to a motor tractor.

**Fludd** OR **FLUD**, **ROBERT** (1574-1637). An English physician and mystic. Born at Bearsted, Kent, he was educated at S. John's College, Oxford, and took his degree of M.D. at Christ Church. He studied chemistry abroad, where he adopted many of the views of Paracelsus (*q.v.*). Returning to England in 1605, he became a fellow of the College of Physicians. Known as "the Searcher," under the name of Robertus de Fluctibus, he wrote many works in Latin, engaged in controversy with Gassendi, Kepler, and Mersenne, and is believed by some to be the inventor of the barometer. As the supposed author of the *Summum Bonum*, 1629, and an apology for Rosicrucianism, 1617, he is credited by De Quincey with being "the immediate father of Freemasonry." He founded a philosophy on the Hebrew scriptures. He died in London, Sept. 8, 1637. See *Freemasonry*; *Rosicrucians*; consult also Robert Fludd, *Life and Writings*, J. B. Craven, 1902.

**Flüela**. Mt. pass of Switzerland, in the canton of Grisons. It extends between the Schwarzhorn and the Weisshorn, on the carriage road from Davos to Sus. On the latter mt., at an alt. of 7,835 ft., is the Flüela hospice. The road has refuge galleries, used in winter.

**Flüelen**. Village of Switzerland, in the canton of Uri. It stands at the head of Lake Uri, a S.E. extension of Lake Lucerne, 2 m. N.N.W. of Altdorf on the St. Gothard rly. The port for Altdorf, it is the terminus for lake steamers. The Axenstrasse carriage road, constructed in 1863-65, leads from here to Brunnen. The village has a château and several hotels.

**Fluellen**. Character in Shakespeare's *Henry V*, a Welsh officer in the king's army. Of hasty temper and verbose speech, he is ever ready to compare the fighting of his day with that of the ancients.

**Flügel Horn**. Brass instrument. It is similar to the cornet, but of wider bore, like the bugle, and of mellow, horn-like tone. It is a modern improvement of the key bugle. The soprano instrument is the most usual. The term means wing horn. See *Cornet*.

**Fluid**. That form of matter which takes the shape of the vessel containing it and is characterised by its inability to resist permanently any applied shear stress, however small. Liquids and gases are both known as fluids; a liquid is distinguished by possessing a free surface if it does not completely fill the containing vessel, whereas a gas expands to take up all the available space. Furthermore a liquid is much less compressible than a gas. The distinction between a solid and a liquid is not always easily defined, for some so-called solids actually flow, although at a very slow rate. The flow of pitch at room temperatures is an example, and even lead can be made to flow under certain conditions. See *Flow*.

**Fluid Measures**. Nearly all fluid measures have been derived from corresponding measures of length or weight and suffer all the variations of the latter which were taken from parts of the human body. It is only within comparatively recent times that fluid measures have become standardised by law in different countries. In the United Kingdom the gallon is the unit measure for fluids, and in countries where the metric system is standardised the litre is the unit. A gallon contains a little over four and a half litres. See *Weights and Measures*.

**Fluke**. Group of trematode worms of parasitic nature, usually leaf-shaped. One, the liver fluke (*Fasciola hepatica*), in its adult condition lives in and devours the liver of the sheep, causing the much-dreaded "rot." The eggs pass out of the body of the sheep with the dung, and if they fall in a wet place hatch out into tiny ciliated embryos that swim about in search of a small water snail (*Limnaea truncatula*), perishing in about eight hours if unsuccessful. Within the body of such a snail other stages of life are passed, until finally one shaped like a minute tadpole is attained (*cercaria*). This leaves the snail and swims to a stem or leaf of grass, to which it attaches itself, and passes into an encysted or dormant stage. Its tail

has gone, it is covered by a hard coat, and resembles the adult fluke except in size.

Should a sheep swallow one of these capsules or cysts, the resistant covering is dissolved by the gastric juice, and when it passes into the small intestine the tiny fluke makes its way up the bile-duct into the liver of its victim, there to increase in size and become sexually mature. The disease may be entirely prevented by keeping sheep away from damp, ill-drained land. As there is no cure for the disease, sheep showing signs of rot should be slaughtered as soon as possible. See *Sheep*.

**Fluoranthene** OR **IDRYL** ( $C_{15}H_{10}$ ). Substance found in coal-tar and in the residue known as "stuppfeet" obtained after the distillation of mercury ores. Crude pyrene from coal-tar is converted into the picric acid compound, whence the fluoranthene is obtained in the free state and re-crystallised.

**Fluorescein**. An aniline dye formed by heating five parts of phthalic anhydride with seven parts of resorcinol at a temperature of 200° C. When the reaction has taken place the mass becomes solid and forms a dark-brown cake. The solution in alcohol or alkalis exhibits a brilliant yellow-green fluorescence from which the substance takes its name. It is used as a dye for wool and silk—but the colour is not fast—and for preparing the liquid in druggists' show bottles. The sodium salt is used in ophthalmic practice to render visible damaged portions of the transparent cornea of the eye.

**Fluorescence**. The property possessed by many organic or inorganic substances of emitting visible light when subjected to ultra-violet radiation. If this emission continues after the removal of the source of the ultra-violet rays, the phenomenon is called phosphorescence (*q.v.*). Both classes of substance are included under the term phosphors (*q.v.*). Synthetic inorganic phosphors are outstandingly efficient, but many natural minerals fluoresce and a few show phosphorescence.

All having a crystalline structure, their fluorescence is believed to be caused usually by the presence of an impurity, such as copper or manganese, in the lattice. This impurity is known as an activator. Ultra-violet radiation excites these fluorescent centres by increasing the energy of certain electrons. After excitation the electrons return quickly to their normal

Flügel Horn. Improved model of B flat horn

By courtesy of Hawkes & Son

condition, giving up the induced energy in the form of visible light. In phosphorescence the energy of excitation is stored before being released in a similar manner.

Although at least 60 mineral species have shown fluorescence (including uranium and other radio-active minerals), only two, scheelite and powellite, invariably fluoresce. As scheelite is an important ore of tungsten and often resembles the worthless minerals with which it commonly occurs, its fluorescence has been used as a means of detection and for prospecting. Portable short wave ultra-violet lamp units are used underground in several mines. The colour of the emitted light may vary for the same mineral; scheelites have been examined which fluoresce with a blue, yellow, or brown colour; fluor spar often gives a purple; some calcites pink; uranium minerals, yellow or green. Crude petroleum is fluorescent, and oils can be correlated with specific sand beds by their fluorescent colours. Applications of fluorescence in biology, medicine, etc., are numerous. Consult Fluorchemistry, J. de Ment, 1945.

**Fluorescent Lamp.** Method of illumination. Attempts were first made over a century ago to design a discharge tube that would act as a practical illuminant. Moore in 1904 came near success with his long tube of up to 180 ft., supplied by a high voltage transformer, but two difficulties still had to be overcome. The light efficiency was not sufficiently high in comparison with other lamps, and the residual gas filling of nitrogen or carbon dioxide gradually disappeared. Both defects have been removed by the modern fluorescent lamp.

It was found by Claude in 1910 that if one of the inert gases (helium, argon, neon, krypton, or xenon) was used as the residual filling, this disappearance was almost negligible. The addition of mercury to neon, or to neon and argon mixed, improved the efficiency and the colour, while the vacuum remained sufficiently constant for at least 1,000 hours. Secondly, the discharge from these gases was found to contain a large ultra-violet component, and a coating of special powder on the inside of the tube makes use of the invisible rays by fluorescing brightly, greatly increasing efficiency and enabling the colour to be widely varied.

The first powders were sulphides of zinc and other metals; but

more efficient "phosphors" of silicates and tungstates were discovered by J. T. Randall in 1936. The improvement is indicated by the luminous output in lumens per watt: Gas-filled filament lamp—11 Ln/W; fluorescent lamp using "green" sulphide coating—15 Ln/W; fluorescent lamp using "green" silicate coating—50 to 60 Ln/W. The modern Jenkins lamp uses pure neon, with coating of zinc orthosilicate or calcium tungstate, and possesses long life as well as high efficiency. Standard dimensions of the tubes for indoor lighting are 9 ft. long by 20 mm. diameter, but other lengths and shapes are made. Consumption is about 40 to 60 W. Many shades of colour may be obtained, including daylight.

To start these lamps, a striking voltage from 1.5 to 2 times the running value is necessary. The two voltages are obtained automatically by the use of a series choke, or by designing the step-up supply transformer with a high leakage reactance. A few seconds after switching on the tube has fully lit up, and the voltage becomes normal. Shorter and more powerful lamps are used for outdoor illumination.

**Fluorides.** Salts of hydrofluoric acid. They are prepared by acting on a metal, or its oxide hydroxide or carbonate, with hydrofluoric acid. Calcium fluoride ( $\text{CaF}_2$ ) occurs native as fluor spar or "blue-john," and from it most of the preparations of fluorine are made. The fluorides of the alkalis are soluble in water and are employed with mineral acids or acetic acid in the processes of etching glass. Some fluorides are gaseous at ordinary temperatures, but most are stable bodies, and are not decomposed by heat. A series of double fluorides is known. Fluorides are recognized by the evolution of hydrofluoric acid on heating with sulphuric acid.

**Fluorine.** Gaseous element of greenish-yellow colour, first isolated by Moissan in 1886. Its chemical symbol is F; atomic weight 19, atomic number 9, boiling point  $-187^\circ \text{C}$ . Derbyshire-spar or "blue-john" is calcium fluoride. Cryolite, a double fluoride of aluminium and sodium, is found in Greenland, and the element occurs widely throughout the mineral kingdom, but only in small amounts. Scheele in 1771 first recognized that fluor spar is a fluoride of calcium and prepared hydrofluoric acid, but all attempts to prepare fluorine were unsuccessful before 1886. It was liquefied in

1897 and solidified in 1903. The difficulties to be faced in preparing fluorine are very great on account of the extremely active chemical affinity it has for glass and most metals. Traces of the gas are very irritating to the mucous membrane, and if brought into contact with the skin the gas causes a bad burn. Alcohol, ether, benzene, and turpentine take fire on contact with fluorine. Moissan isolated the element by the electrolysis of anhydrous hydrofluoric acid to which acid potassium fluoride had been added in order to make the liquid conduct the electric current. One compound of fluorine and hydrogen is known, and one oxide,  $\text{F}_2\text{O}$ , has been prepared. Although fluorine is akin to chlorine in many properties, there are no fluorine compounds corresponding to hypochlorites and chlorates.

**Fluorite or Fluorspar.** The natural form of calcium fluoride ( $\text{CaF}_2$ ), crystallising in the isometric system. It occurs as colourless, green, blue, purple, or yellow crystals, generally massive. It has an excellent cleavage, is fairly soft, and often fluoresces blue in ultra-violet light. Fluorite is a common accessory mineral in sedimentary (dolomites and limestones) and acid igneous rocks; also found associated with ores of lead, silver, zinc, and tin, in mineral veins. Fluorite is used as a flux in the making of steel; in the manufacture of opalescent glass and enamels, and the preparation of hydrofluoric acid. The dark blue variety from Derbyshire, "blue-john," is used for ornaments.

**Fluoroscope.** Apparatus for the analysis of clear liquids and various materials as they fluoresce when exposed to ultra-violet light. Certain chemicals have the quality of fluorescing, or glowing, when X-rays strike them. Thus, if a plate covered with zinc sulphide is held on one side of a human hand, and an X-ray tube is operating on the other side, the bones of the hand will be outlined on the plate as shadows. As the X-rays do not penetrate the denser bone structure as intensely as they do the flesh, the bones show up as shadows on the plate. This principle is used in fluoroscopes for examining the interiors of objects. Commercial fluoroscopes can detect flaws in metals, alterations in documents, and the contents of cases and packages passing through the customs. Minerals subject to the action of a fluoroscope glow with light and colour which in ordinary daylight is unsuspected.

**Flushing.** The action of cleansing a sanitary fitting or drain by a sudden flow of water, usually from

Flushing. Fig. 1 (top). Section through bell-siphon flushing cistern. Fig. 2 (below). Section of inverted U-tube siphon flushing cistern

a cistern fitted with hand-operated or automatic discharge mechanism. Cisterns used with water closets have 2 to 3 gallons capacity as determined by the water supply authority. The flushing mechanism is commonly of a waste-preventing design, capable only of siphonic discharge.

Two typical arrangements are shown in Figs. 1 and 2. Siphonic action is induced by the movement of a small quantity of water down the vertical stand-pipe that passes through the bottom of the shell. The fall of this water sets up a slight downward movement of the air within the stand-pipe and the flush pipe connecting the cistern with the fitment it serves. This momentary lessening of air pressure within the stand-pipe provides the lack of balance necessary for siphonage. In consequence, the atmospheric air pressure bearing upon the surface of the water in the cistern is able to force the whole content of the cistern upwards into the stand-pipe and down the flush pipe.

In Fig. 1, the lever action that raises the bell must be followed by a quick release action, so that the descending bell may splash the requisite quantity of water into the stand-pipe. The better and quieter arrangement of Fig. 2 operates on the pull of the lever. This action raises a valved plate inside the wide, open-ended cylinder, and so lifts the water above the plate over the inverted U-tube and into the stand-pipe.

Compact flushing valves regulated to discharge only a predetermined quantity of water frequently

require a greater pressure of water than is ordinarily available. Automatic flushing is largely confined to public urinals, and to drains that cannot be laid with a self-cleansing gradient. These are commonly fed with a drip supply of water regulated to flush a urinal every 15 to 30 minutes, and to provide a drain flush once or twice in 24 hours. Several automatic flushing devices resemble the bell and stand-pipe arrangement of Fig. 1. In an automatic tank, the water would rise above the fixed, parallel-sided bell, and compress the air in the stand-pipe till the sudden discharge of this air established a siphonic discharge action.

**Flushing** (Dutch, *Vlissingen*). Seaport of Holland. On the S. coast of the island of Walcheren, it lies at the mouth of the Schelde, in the province of Zeeland. In normal times it is linked by steamer with Harwich and Folkestone and has through rly. connexion to Rotterdam, Amsterdam, and the N. of Europe generally. Except for ship-building and some rly. workshops, the town has little trade, but it is of considerable strategic importance, as its history shows. It also developed before the First Great War as a sea-bathing resort. Pop. 22,554.

In the history of the Netherlands Flushing was often prominent, especially as a naval base. It was the birthplace of Admiral Ruyter, 1607, and on the sea wall there is a monument to him which survived the Second Great War. The town was severely bombarded by an English fleet under Lord Chatham in the Walcheren expedition of 1809, but the subsequent attempt to capture Antwerp from there failed completely. The town suffered badly in the Second Great War, its port being completely

destroyed by Allied bombing and deliberate wrecking by the Germans. The dykes on both sides of Flushing were repeatedly bombed on Oct. 7, 1944, British and Canadian forces subsequently landing at Flushing on Nov. 1 and clearing the town of Germans on Nov. 4. Rly. connexion with the N. of the Netherlands was restored in the autumn of 1946.

**Flute** (Lat. *flatus*, blast). Family name of many wind instruments of the whistle type, whether blown vertically through a mouthpiece or transversely through a side hole.

Down to the end of the 18th century the number of flutes employed in the orchestra was uncertain, and on account of their weak tone several of them were often used in unison; but the modern instruments are so much improved that it is now customary to employ them singly, and the two (or occasionally three) flutes of the modern orchestra play independent parts. Flutes have been made at various

Flute. 1. Military flute, 19½ ins. 2. Military fife, 15 ins. 3. Piccolo or octave flute, 12 ins.

itches, but the scale of the open finger-holes is always called D. The transposing of flutes, other than the concert flute of ordinary pitch, has been usually reckoned from D instead of from C. Originally, the six finger-holes were the only means of obtaining a scale, and chromatic notes had to be made by cross-fingerings, half stops, and other unsatisfactory means; but key after key has been added until now all the semitones are producible, in good tune and with even tone. The convenient compass of the concert

Flushing. Dutch housewives in the fish market on the Nieuwendijk, a view taken before the Second Great War

flute is as shown, and three semitones higher are possible. The flute is the most agile of the wind instruments, modern mechanism having reduced finger difficulties to a minimum. Flute is also the name of an organ stop imitating the tone of the orchestral instrument of the same name. A flûte-à-bec is a beaked flute, or flute with a mouthpiece, played vertically. See Fife; Flageolet; Organ; Recorder.

**Fluting.** In architecture, flutes are grooves in a column, separated usually by fillets. Fluting is generally vertical, but spiral fluting occurs in Norman architecture. See Architecture; Column.

**Fluvial Deposits** (Lat. *fluvius*, river). In mining geology, term for deposit of minerals dissolved from primary sources by streams etc., and laid down in concentrated masses. Such mineral concentrations are richer than those found in eluvial deposits (see Eluvial Deposits), in the formation of which flowing water plays no part.

In geology, fluvio-glacial deposits are those layers of mud, etc., thrown up by streams emerging from the terminations of glaciers. According to the slope of the glacier and the speed of its streams, the deposits' layers vary, but the

coarsest elements always fall nearest the glacier or, if discharged into water, at the base of a conical mass which is topped by the least coarse.

Fluting in Ionic column; inset, plan of fluting

**Flux.** Material used in metallurgical smelting, refining, brazing, soldering, and welding operations, to remove unwanted matter or to protect the metal from the atmosphere.

Mixed with the metalliferous portion of an ore, there are many other gangue minerals, which

must be removed as a slag to give clean, reduced metals. By themselves these earthy substances are usually too refractory to allow easy fusion and so fluxes must be added to combine with them, producing an easily melted, free-running slag, readily separated from the molten metal. If the ore is acidic, basic fluxes, e.g. limestone, iron oxide, or soda, are required to combine with the silica, etc., while a basic ore needs acidic substances, such as quartz or sand. Neutral fluxes, such as fluorspar or borax are sometimes added to lower the melting point of the slag. Similar considerations apply in refining and melting. Welding, brazing, and similar joining operations require fluxes to break down oxide films, and to protect the hot joint from the atmosphere. An example is the use of zinc chloride for tinning. See Gangue.

**Fluxion.** Term used by Sir Isaac Newton to signify the rate at which a "fluent" (or variable) increased or decreased at any given instant. The fluxion is thus the derivative of the fluent with respect to time ( $\dot{x} = dx/dt$ ;  $\ddot{x} = d^2x/dt^2$ , etc.). See Differential Calculus; Newton.

**Fly.** Insect of the order Diptera, characterised by having only fore wings, the hind pair being modified into balancers, or *halteres*, which resemble minute drumsticks. These are sensory organs that enable the insect to maintain

equilibrium in the air. Removal of the halteres causes some flies to lose their power of balance when in flight; others fall aimlessly to the ground. The mouth-parts are adapted for sucking up liquid food, and in mosquitoes and horseflies they include sharp lancet-like organs which enable the insects to pierce the skin of man and other vertebrates in order to imbibe blood. The pathogenic agents of such virulent diseases as malaria, sleeping sickness, yellow fever, and elephantiasis are transmitted to man through blood-sucking flies.

Flies undergo complete metamorphosis: their larvae are always devoid of legs, and those of the house-fly and blowfly, for example, are without an evident head and are known as maggots. In gnats or mosquitoes, and among midges, the larvae are aquatic, and are variously modified to suit that mode of life.

In several families, the larvae are parasites living in the bodies of mammals (botflies and warbleflies), or in other insects (tachinid flies).

The larvae of many flies are injurious to food crops, notably those of the craneflies, known as leather-jackets; the fruitfly, to oats; the goutfly, to barley; and the beet or mangold fly. About 85,000 different species of flies are known, over 5,200 kinds occurring in the British Isles. See House-Fly.

**Fly.** The largest known river of New Guinea or Papua. It rises among the Victor Emmanuel Mts. in the E. part of the island, and flows S.W. and then S.E. to discharge its waters into the Gulf of Papua by a long, wide estuary. For part of its course it forms the frontier between Dutch and British New Guinea. It has a length of about 620 m., and is navigable for small craft nearly all the way. The principal affluents are the Aice and Strickland rivers.

**Fly-agaric** (*Amanita muscaria*). Large toadstool of the family Agaricaceae. It has a creamy-white stem and gills, the former with a broad soft frill around its upper part. The upper side of the cap is orange-scarlet, flecked with irregular particles of white—the remains of an outer envelope. Well known as a poisonous species, it was formerly employed for

Fly-agaric. The poisonous scarlet toadstool, *Amanita muscaria*

poisoning fly-papers. It has also intoxicating properties, and is used in Kamchatka in preparing vodka.

**Flycatcher.** Name of family (*Muscicapidae*) of small birds, including nearly 300 species. All feed upon insects, which they usually catch on the wing. The tail is in most species considerably shorter than the wing, and

while the European species are plainly clad in sombre hues, some of the tropical ones are very gorgeous. The pied flycatcher (*Ficedula hypoleuca*) comes to Great Britain in the spring, the spotted flycatcher (*Muscicapa striata*) in the summer, and the red-breasted flycatcher (*Siphia parva*) is occasionally seen in autumn. See Egg, colour plate.

**Fly Fishing.** Fishing with an artificial fly. The flies are made of feathers, silk, tinsel, fur, and other materials. Trout-flies, especially those used in the dry-fly method, are made to resemble as closely as possible some form of fly or other aquatic insect.

The fly, which is attached to the line by a cast of gut of a thickness varying with the shyness of the fish, the colour of the water, and other conditions, may be either sunk deeply in the water, or fished wet near the surface, or floating. The opinions of experts differ about the value of colour in artificial flies, as compared with their size and form, but all agree that the principal factor in success is the way in which the fly is presented to the view of the fish. Recent experiments in underwater photography have done much to confirm the view that, when fished "dry" or floating, the important factor is the fly's silhouette as seen against the light.

It is essential in fly fishing for the angler to keep himself and his rod out of sight of the fish, and this condition is usually ensured by keeping low when fishing up or across a stream, and by using a long line when fishing down stream or casting over a loch. Correct casting requires skill which can be attained only by practice. Where the surroundings permit, the rod can be kept up and the cast made overhead; it can also be made underhand, or the line can be got out by the Spey throw or other such methods, such as the downward cut employed against the wind. The best sport to fishermen with the fly in the United Kingdom is given by salmon, sea-trout, brown trout, and grayling.

Fly fishing with natural flies is another method, but, owing to the difficulty of keeping them on the hook when casting, the method of dapping is employed. The fly is dropped on the water and raised

again with a short line, or a long rod is used with a light blow-line, taken out by the wind. See Angling; consult also Fly Fishing, K. Rollo, 1946; New Lines for Fly Fishers, W. B. Sturgis and E. Taverner, 1946.

Flycatcher. The pied flycatcher, a spring visitor to Great Britain

**Flygare-Carlén, EMILIE SMITH** (1807-92). Swedish novelist. Born at Stroomstad, Aug. 8, 1807, in 1827 she married Axel Flygare, and was left a widow in 1833. She published her first novel, Vladimir Klein, in 1838, under the pseudonym "Fru F." In 1841 she married John Gabriel Carlén, lawyer and man of letters, and continued to write stories, largely concerned with the life of the Norwegian coast. She died at Stockholm, Feb. 5, 1892. Many of her novels have been translated into English, including *The Rose of Tistelon*, 1844; *The Birthright*, 1851; *The Guardian*, 1865. Her collected novels were published in 31 vols., 1869-75, and her *Reminiscences* in 1878.

**Flying-Boat.** A class of sea-going aeroplane, the essential feature of which is a boat-like hull. The majority of modern seaplanes, especially the larger designs, are flying-boats; float seaplanes or floatplanes being the other main division.

The hull provides buoyancy on the water, and also takes the place of the fuselage of the landplane,

normally accommodating the crew, passengers, and/or freight or armament. The flying-boat has small wing-tip floats which may be retractable in flight, or alternatively sponsons on the side of the hull itself. Flying-boat designers and operators have adopted many of the terms of marine engineering, including keel, chine, bow, stern, etc. The keel has one or more steps breaking its outline; a flying-boat takes off from and alights on the planing bottom, which is in advance of the front step. The engines and airscrews must be kept clear of spray, and these are therefore slung high; the same applies to the tail surfaces.

As a flying-boat is independent of runways and airfield restrictions, many of the world's largest aircraft have come into this category—examples were the Dornier Do X of 1929, which once carried 169 passengers, and in 1947 the Hughes Hercules (wing span 320 ft.), a major experiment in ship-building as well as aeronautical engineering. The most notable British flying-boat and the largest standard R.A.F. aircraft during the Second Great War was the Short Sunderland (see Aeroplane illus.; Sunderland), a military development of the outstanding commercial Empire boat. The Vickers-Supermarine Walrus was an amphibian flying-boat, with a retractable wheeled undercarriage permitting operation from land airfields, aircraft-carriers, or the water. See Seaplane.

**Flying Bomb.** Name given to a jet-propelled weapon used during the Second Great War. Experiments were made in Great Britain in 1916 and in the U.S.A. in 1918 with pilotless aircraft, and in Great Britain about 1926-27 with a radio-controlled pilotless bomber called Larynx, but none of these was further developed. During the Second Great War, however, the Germans invented what they called *Vergeltungswaffe Eins* (V 1, or Reprisal Weapon One), giving it the code number FZG-76. Frequently referred to in Great Britain as the V 1, it was officially named in that country the flying bomb. Other names, more colloquial, included buzz bomb and doodlebug.

The flying bomb had several wing variations. One model had 16-ft. span wings, tapering in plan from the body to cut-back wing tips; the other had parallel chord 17½-ft. span wings. Sharp steel strips were fitted inside the wings' leading edges to cut

balloon cables. No model had ailerons. Other dimensions were: fuselage, length 21 ft. 10 ins., and maximum diameter 2 ft. 8½ ins.; propulsion unit, 11 ft. 3 ins. long, 1 ft 10½ ins. maximum diameter; the jet tube projected behind the rudder, and the overall length was 25 ft. 4½ ins.; tail plane span, 7 ft. 5 ins. Almost entirely of mild-steel sheet, the nose section, containing the magnetic compass, was of duralumin, to reduce compass deviation. Gross weight was 4,700 lb. made up thus: shell, about 1,800 lb., explosive 1,870 lb., fuel about 950 lb. with tankage for about 130 gallons.

The propulsion unit was a simple welded-steel casing mounted above the rear of the fuselage on a front fork and on the fin aft. Air, compressed at very high initial pressure and contained in two wire-reinforced spherical bottles, forced fuel from the tank through pipes running up the front support of the propulsive-unit. This fuel was sprayed into the combustion chamber through nine atomiser jets arranged in three rows of three between a venturi grill. Three compressed-air jets for starting the engine were mounted above the topmost fuel jets. In front of the jets was a square "honeycomb" of non-return valves made of 126 double leaves of pen-nib steel, with each double leaf pressing its two inner edges together. In front of this honeycomb was the circular air intake.

The fuselage contained six sections for the compass, warhead, fuel tank, air bottles, gyroscopes and controls, and servo-motor. Under the fuel tank centre-section a fore-and-aft launching rail with thick metal sides tapered from front to rear.

Flying Bomb. The machine climbing after being launched from its ramp on the French coast

Flying Bomb. Sectional drawing of the pilotless plane used by the Germans to bombard London in the summer of 1944

Flying bombs were brought from assembly shed to launching ramp on a trolley. A derrick travelling on rails, one on either side of this ramp, lifted them on to the ramp by the lug above the wing spar. The gyroscopes were driven by compressed air from the air-bottles in the adjoining section. Bearings from the repeater compass in the nose were used to maintain the course through the master gyroscope (*see* Automatic Pilot). A pre-set aneroid barometer controlled the height of flight, and an air log set to the estimated distance governed range.

Launching was controlled from a blast-proof control-house about 30 yards from the upward inclined ramp, and was effected by a piston driven by compressed air within a cylinder that ran the full length of the ramp. A sprag on the piston projected through the upper wall of the cylinder and engaged with the launching rail of the flying bomb. At the end of its run on the ramp the flying bomb rose abruptly into the air, and climbed to its pre-set height before flying level. But not all flying bombs started successfully; a number fell back, causing damage to the launching sites and injury among the launchers.

Launching speed was about 185 m.p.h., and had to exceed 170 m.p.h. to open the air valves and start the normal operational cycle of the engine. During flight, the air log was rotated backwards by a calibrated air-screw of about 12 ins. diameter mounted in front of the fuselage nose. When the estimated range had been flown and zero reached on the log detonators attached to the tail plane were electrically fired. These forced down two

control tabs, which in turn forced the bomb into a dive. The warhead had (1) a sensitive impact fuse; (2) a universal mechanical fuse with one switch at the nose and another under the warhead to detonate if the flying bomb should glide into the ground; and (3) a clock fuse to explode the bomb after two hours should the others fail. A few weapons carried small radio transmitters, enabling German receiving stations to plot their flight.

Exploding on contact, the flying bomb made only a small crater when it landed on open ground, but the lateral blast covered a much wider area than did that of bombs of deeper penetration.

Early in 1943 British Intelligence learned through information supplied by foreign workers forced to labour in Germany that Germany was preparing a long-range weapon to bombard London. Through agents the zone, and through R.A.F. reconnaissance the exact site, of the principal experimental station was located at Peenemünde (*q.v.*), near Stettin, on the Baltic coast.

Air reconnaissance also revealed large ferro-concrete structures at Watten, in the Pas-de-Calais, and about 100 smaller structures behind the French coast between Le Havre and Calais. It was presumed that these were for the launching of jet-propelled weapons, while it was thought that the large structures were to fire rockets. All launching ramps pointed towards London. The R.A.F. and the U.S.A.A.F. heavily attacked both Peenemünde and the launching ramps, destroying all these permanent launching sites, and forcing the Germans to build

smaller but less efficient launching structures which could be rapidly assembled and camouflaged.

Just after 4 a.m. on June 13, 1944, two Royal Observer Corps members on duty at Dymchurch, Kent, spotted a flying bomb approaching, identified it instantly, and reported within 35 secs.; it proved to be the first missile of an intensive attack lasting seven weeks, and twice reaching a maximum of 200 bombs a day, aimed at London. Plans made to meet the anticipated attack were immediately put into effect.

The flying bombs flew at a height of between 800 and 2,500 ft. at a speed varying with the direction of the wind from 320 to 400 m.p.h. This was both higher and faster than had been anticipated, and they proved difficult targets for the heavy A.A. guns detailed for the defence. The defences were therefore swiftly reorganized. (See Anti-Aircraft Command.)

Beyond the coastal gun belt, fighters had the task of destroying flying bombs which had passed the guns. They found the best method of attack in a dive at an acute angle from behind, which gave them speed in excess of the bomb.

Determining the range at night was difficult, until Prof. Sir Thomas Merton invented a simple range-finder, costing about one shilling. Four types of fighter aircraft were used: the Tempest, Mustang, Spitfire XIV, and the jet-propelled Meteor. They destroyed 1,900 flying bombs, Tempests with a total of 578 brought down proving most effective, Spitfires next with over 300.

A curtain of barrage balloons, eventually totalling some 2,000, was set up to the S.E. of London, between Godstone in Surrey and the Thames near Woolwich. Their cables brought down 278 flying

bombs. (See Balloon Defences.)

Very few flying bombs were launched from France after Sept. 4, by which date the Germans in the Pas-de-Calais had been cut off from their bases by the advance of the Allies. It was estimated that from June 13 to Sept. 4, 1944, a total of 8,070

Flying Bomb. Its pre-determined range having been reached close to London's Law Courts, a flying bomb dives to earth and explodes in a cloud of black smoke. These photographs were taken from a Fleet Street roof in July, 1944

flying bombs had been launched, sometimes singly and sometimes in waves. 25 p.c. were erratic or inaccurate, and 46 p.c. were brought down by the triple defences. On Aug. 28, 97 out of 101 launched were destroyed. During the last fortnight of the main attack, only 45 p.c. of the bombs launched crossed the English coast.

Croydon was the worst-hit borough (See Croydon illus.), Wandsworth the worst-hit London borough. Several flying bombs fell in Norfolk, and one fell at Northampton. Flying bombs destroyed in S.E. England 23,000 houses, damaged more than 1,100,000.

After the main attack was over, a few flying bombs arrived from a more easterly direction, including a number which fell in S. Lancs on Christmas Eve, 1944. These were all launched from adapted Heinkel 111 bombers. Bomber Command attacked the aerodromes from which the Heinkels operated, intruder fighters patrolled the Dutch and Belgian coasts at night, and guns were deployed in the zone of the Thames estuary.

But the main attack by flying bombs was switched against Antwerp (*q.v.*) and, during the German counter-attack in the Ardennes in Dec., 1944-Jan., 1945, to Liège.

**Flying Buttress.** In architecture, a half arch used to transmit the thrust or pressure of a structure, usually a vault, to a main buttress or solid foundation. Flying buttresses were first used in France in the 12th century, and formed a principal decoration of the exterior of French cathedrals. See Buttress.

**Flying Column.** Body of lightly equipped, mobile and self-supporting troops which operates for

short periods at a distance from its base. Such bodies are necessary when armies are engaged over a wide theatre of operations or are employed in suppressing guerrilla warfare. Flying columns are frequently detached from the main army to go to the relief of a beleaguered garrison. During the Second Great War the most notable were the Long Range

Desert Group (*q.v.*), which carried out raids behind the enemy lines in N. Africa, and the Chindits (*q.v.*), who performed similarly against the Japanese in Burma.

**Flying Dutchman, THE.** Spectral ship traditionally haunting various seas. It is generally associated with the latitude of the Cape of Good Hope, about which it was said to be ever moving under crowded canvas, unable to reach port. The vessel was supposed to be thus doomed owing to the abominable acts of her crew headed by their captain, Vanderdecken. Her appearance is deemed a portent of disaster. The legend was dramatised in *The Flying Dutchman* by Douglas Jerrold, 1829, and later by Edward Fitzball; Captain Marryat founded on it his story, *The Phantom Ship*, 1839; and it inspired Wagner's opera, *The Flying Dutchman*, 1844.

**Flying Fish.** Any member of several groups of tropical fishes. Many species have the pectoral fins so lengthened as to resemble wings. They are in the habit of leaping out of the water to escape their

enemies, and taking long skimming flights above the surface, supported by their distended fins, which are not used as propelling agents.

**Flying Fortress.** American heavy bomber of the Second Great War. Known to the U.S. army as the B-17 and officially designated Fortress in the R.A.F., the first model of this Boeing bomber in operational service in Europe proved under-armed<sup>1</sup> and could carry only 12,800 lb. of bombs. Later types, the B-17E, F, and G, formed the backbone of American bomber strength, especially in mass daylight raids on Germany. Improvements included an armament of at least twelve 5-in. machine-guns, and a standard bomb-load was 6,000 lb. The four engines were of the 1,200-h.p. Wright Cyclone type; wing span was 103 ft. 9 ins., length 74 ft. 9 ins. From the same designers came the much larger Superfortress (*q.v.*). See *Aeroplane* *illus.*

**Flying Fox.** Erroneous name for the fruit bat, of the genus *Pteropus*. It is due to the fact that the head slightly resembles that of a fox. Unlike other bats, which it greatly surpasses in size, it feeds entirely on flowers and fruit. It is found in S. Asia, the E. Indies, Madagascar, Australia, and some of the Pacific islands. The largest species, that of Malaya, *Pteropus edulis*, measures over 5 ft. between

Flying Fox: the Malayan species

the tips of the wings, and is considered a great delicacy. The fruit growers of Australia suffer much from its depredations. The name is sometimes wrongly given to the Flying Phalanger (*q.v.*). See *Bat*.

**Flying Lemur** (*Galeopithecus*). Popular name for the cobao of Malaya, only member of the order Dermoptera. The loose skin along the sides of the body and neck spreads into a kind of parachute when the animal launches itself into the air, enabling it to cover at one bound as much as 70 yds. from tree to tree. It feeds on leaves.

**Flying Officer.** Commissioned rank in the R.A.F. above that of pilot officer and immediately below

that of flight lieutenant. It replaced the rank of observer officer in 1930. A flying officer's rank is indicated by a single ring, slightly wider than that of a pilot officer, on the sleeve or epaulette.

**Flying Phalanger** (*Petaurus*). Small squirrel-like opossum, of which there are three species, found only in Australia and New Guinea. It is able to take long gliding leaps through the trees, partly supported by a membranous extension of skin. It feeds upon insects, fruit, and blossoms.

**Flying Speed.** Normal speed which an aeroplane must maintain in order to remain in the air, or the actual air speed of a machine necessary for its support in the air. This must not be confused with the apparent or ground speed of the machine. See *Airspeed*.

**Flying Squad.** Mobile section of a police force equipped with fast cars for dealing with smash-and-grab thieves and sudden outbreaks of crime. The first flying squad was established by the London metropolitan police in 1919, and similar organizations were adopted throughout Great Britain. Flying squad cars, which bear no outward indication of their police duties, are equipped with concealed radio which enables them to keep in constant touch with headquarters.

At New Scotland Yard there is a plotting table which shows the position of every car on patrol. When a crime is reported to the control room, the time and place of its commission, with any available details of the criminal, are transmitted by radio to the squad car nearest to the scene. With the development of television, experiments have been made in the transmission to cars of photographs of wanted criminals. The picture appears on a small panel on the dashboard and remains there until another message is transmitted. Autogiros have been introduced into the flying squad,

Flying Lemur, Galeopithecus, with skin distended for gliding

primarily to assist in traffic control, but also to direct converging squad cars.

**Flying Squid** (*Ommastrephes sagittatus*). Species of squid or

Flying Squid. A cuttle fish which springs out of the water

cuttle fish. Long and narrow in shape, it is common in the open seas, and forms an important part of the food of the sperm whale. It is often called the sea arrow, from its habit of darting backwards out of the water for a considerable height.

**Flying Squirrel** (*Pteromys*). Name given to a number of species found in N. America, Asia, E. Europe, and Africa, and not closely related. Members of this group are able to simulate flying by the ex-

Flying Squirrel of North America. It is nocturnal in habit

tension of the loose, lateral folds of their skin. All are nocturnal in habit. See *Squirrel*.

**Flying Training Command.** Organization established by the R.A.F. in May, 1940, for the training of pilots, observers, and air-gunners. The command was in six groups, one of which dealt with initial training for all categories of air crew; two with elementary flying training; two with service flying training; and the sixth included the observer, bombing, and gunnery schools. Central flying schools, from which R.A.F. flying instructors must qualify, were also in this command. Men passing out of the Flying Training Command were posted to operational training units, where bomber crews were formed to train as teams in aircraft actually on operational service. In 1947 the command was equipped with Boulton Paul jet-propelled training aircraft.

**Flying Wing.** Aircraft consisting of a single triangular wing. The fuselage is integral with the wing and does not normally project beyond the leading and trailing edges. The aircraft has no tail assembly of fin and rudders, small vertical surfaces being mounted at

each wing tip. Aircraft of this type can be powered by either piston engines or jet turbines. During the Second Great War the American Northrop company tried an experimental all-wing aircraft known as the N.I.M., and in 1946 produced a 104-ton tailless bomber for the U.S.A.A.F. In Great Britain the Armstrong Whitworth company, experimenting with flying wings, designed a commercial aircraft to carry a payload of 130,000 lb. at 400 m.p.h. The main advantage of the tailless aircraft is the reduction of structural weight and air resistance. This advantage, however, is scarcely appreciable in aircraft of less than 250,000 lb., hence the great size of all projected aircraft of the flying wing type. See *Aeroplane illus.* p. 136.

**Flysch.** Geological formation. It consists of enormously thick series of sandstones and shales, occurring in the Alps, Apennines, Carpathians, Istria, Dalmatia, Bosnia, Greece, Asiatic Turkey, Caucasus, stretching through S. Asia and still farther East. Their exact age is uncertain, but varies from lower Cretaceous to middle Tertiary. They represent a phase of deposition of sediments of long duration and great geographical extent.

**Flywheel.** In engineering a rimmed wheel mounted on a shaft which is subjected to, or has to exert, a turning effort more or less intermittently. The turning moment (or torque) of an engine on the driven shaft varies during a revolution, the variation depending upon the number and arrangement of cylinders and cranks. If the resisting moment due to the work being done by the driven member is constant, the speed will increase while the driving torque is in excess of the mean, and will decrease while this torque is below the mean. The fluctuation of speed during a revolution due to an increase or decrease of torque decreases with increase of inertia of the rotating parts and can be reduced to any desired small amount by the provision of a flywheel having sufficiently large inertia. This inertia is increased by either increasing the mean diameter of the rim or increasing the weight of the rim, or by both methods. Work is done by the wheel when its speed is reduced, and additional work is stored in the wheel when its speed is increased.

The effect of a flywheel in reducing speed fluctuations is greater at high revolution speeds than at

low speeds; it varies with the square of the revolutions. Thus a high speed petrol engine requires a very much lighter flywheel than, say, a slow speed gas engine of the same power to keep the speed fluctuation low. In some cases (e.g. in marine engines), the inertia of the rotating parts of the engine added to that of the driven member (propeller and shaft) supplies all the flywheel effect required. In some motor vehicles a hydraulic clutch, acting on the principle of the Froude dynamometer, is incorporated in the flywheel, which is known as a fluid flywheel.

**Foal.** Young of the horse and of the ass, of either sex. The term colt has come to be appropriated to the young male animal; filly, a diminutive of foal, to the young female, but formerly the distinction was less rigid. The word is connected ultimately with Gr. *pólos*, foal, and Lat. *pullus*, young animal.

**Foch, FERDINAND** (1851-1929). French soldier. He was born at Tarbes, Oct. 2, 1851, and educated at St. Étienne, at the Collège St. Michel, under Jesuit direction, and at the Collège de St. Clément at Metz. From early years history was his favourite reading.

*F. Foch*

Having enlisted during, but seen no service in, the Franco-Prussian war of 1870, he returned to Metz, but soon entered the engineering and artillery establishment at Fontainebleau. In 1874 he was attached to the 42nd regt. of artillery at Tarbes. Two years later he took a course at a cavalry school at Saumur, and in 1878 became captain of the 10th regt. of artillery. He was picked for the school of war in 1885, and on leaving was appointed to a divisional staff. He was transferred to the general staff in 1894, and later became professor of military history, strategy, and applied tactics at the École Supérieure de Guerre. His lectures there brought him some fame, the bulk of them being collected in two books, *The Conduct of War* and *The Principles of War* (the latter trans. H. Belloc, 1918). Their general argument is that though the art of war is simple, few can acquire it, as its execution demands the highest will, purpose, and strength in a commander who can impart them to his soldiers.

In 1901 Foch was sent to command a regiment. It has been said that his religious beliefs, and the fact that a younger brother was a Jesuit, were the causes of this apparent setback. However, in 1903 he became full colonel, in 1905 chief of staff to the 5th army corps, and in 1907 brigadier-general with a position on the general staff. Clemenceau then offered him the command of the École de Guerre, where he spent an invaluable 4½ years, greatly admired by his pupils. In 1911 he became general of division, in 1912 of the 8th army corps, and in 1913 took command of the 20th army corps at Nancy.

On four critical occasions during the earlier part of the First Great War Foch proved his principles in action: in the abortive French offensive and subsequent defence of Nancy, Aug., 1914; on the Marne, Sept., 1914; with the British at Ypres, Oct., 1914; and on the British right flank on the Somme, July, 1916. It was from the Marne, while in command of the new 9th army which he had formed with great speed and thoroughness, that he sent his famous dispatch: "I am heavily pressed on my right; my centre is giving way; I cannot redistribute my forces. The situation is excellent; I am attacking."

On Sept. 30, 1916, Foch reached the age limit, was awarded the *médaille militaire*, and withdrawn from any particular command, though retained on the active list. In Dec., 1916, he became director of a bureau for the study of inter-Allied problems, and pressed for the creation of a strong Allied reserve. Early in 1918 it was decided to place him in command of such a reserve. Then, as the result of the critical German offensive of March 21, which drove a wedge between French and British, a momentous inter-Allied conference was held at Doullens (March 26), at which Foch was appointed generalissimo of all Allied forces fighting on the western front.

After checking the final German offensive between Reims and Soissons, he launched his decisive counter-offensive on the Marne on July 18, which ceased only with the German demand for an armistice. On Aug. 6 he was made marshal of France. The first German request was made on Oct. 28. Foch communicated with the German plenipotentiaries by radio, met them at Rethoules on Nov. 8, and ensured their acceptance of conditions which he had been

engaged in drawing up for some weeks. On Nov. 11, the day the armistice came into operation, marking the defeat of Germany, the French deputies unanimously voted that Foch had "deserved well of his country."

In Paris on July 14, 1919, he led his victorious troops through the newly reopened gates of the Arc de Triomphe de l'Etoile, and on July 19 rode with Haig at the head of the victory parade in London. Foch never lost his essential calm and poise, which gave to all who met him the sense of a man possessing an inexhaustible reserve of confidence, founded on force of will and clearness of intellect in effective combination. He died on March 20, 1929, and was buried in the Invalides, Paris.

His memoirs were published in an English trans., 1931. There are lives by Sir G. Aston, 1929; B. H. Liddell Hart, 1931. Consult also Foch Talks, Cmdt. Bugnet, 1929.

**Focke-Wulf.** German aircraft manufacturers, with main works at Bremen. Apart from an experimental helicopter, Focke-Wulf attracted little attention until the Second Great War. Two of their products then achieved world fame. The four-engine Fw 200, already in use as a commercial transport and named Condor, was militarised as the Kurier, and, with a range of over 2,300 m. and usually armed with two 20-mm. cannon in addition to machine-guns and  $1\frac{1}{2}$  tons of bombs, was used for Atlantic reconnaissance and anti-convooy attack. Wingspan, 108 ft.; engines B.M.W. or Bramo radials.

The Fw 190, introduced in 1942, became the most successful single-seat fighter of the Luftwaffe. Its compact design (span 34 ft., length 29 ft.) and all-round performance owed much to the then new 1,600-h.p. B.M.W. 801 radial engine. The armament of four 20-mm. cannon and two machine-guns was at that time outstanding. Later the Fw 190 was powered by a 1,700-h.p. Junkers in-line unit—the so-called "long-nosed" Fw 190. The final Focke-Wulf fighter to reach the squadrons was the Ta 152, a completely fresh design capable of over 460 m.p.h. This had an exceptional span of wing to aid high-altitude interception. Long-range tanks, bombs, or rockets could be carried on all these types. See Aeroplane illus. p. 132.

**Focus.** The point at which converging rays meet. A virtual focus is the point from which diverging rays are considered to be directed.

With light rays the two cases are respectively illustrated by means of convex and concave lenses.

Focus. Fig. 1. Convex lens causes light rays to be brought to a real focus ( $F_r$ )

Fig. 1 shows parallel rays of light striking a convex lens and being brought to a real focus  $F_r$ , while Fig. 2 indicates that a concave lens causes the incident rays to

Focus. Fig. 2. Concave lens produces an apparent or virtual focus ( $F_v$ )

diverge so that they appear to come from the virtual focus  $F_v$ . The distance from the focus (or focal point) to the lens is known as the focal length.

In mathematics a focus is a point from which, if lines are drawn to any points on a curve, the lengths of these lines conform to some law. In medicine, it is a part of the body where a disease originates or is most active. In photography, and in the use of such instruments as the micro-

scope and telescope, focusing is the operation by which the lens is so positioned as to give the maximum crispness of detail and definition. The adjustment may be made visually or in conformation to a predetermined scale of distances. See Camera; Lens; Photography.

**Fodder.** Name applied to the bulky part of the food of stock.

Coarse fodder crops, also known as forage, include cereal straws, meadow hay, seeds, and clover hay, all characterised by a high fibre content but useful in promoting a feeling of repletion in the animal. They are distinguished from the green fodders such as pasture grass, lucerne, sainfoin, clover, and green maize, which have a great deal of leafage and are often given in a green condition; lucerne, sainfoin, and clover also making excellent hay. Succulent fodders include mangolds, turnips, swedes, carrots, parsnips, and kohlrabi; in addition to the leaves, the roots of some of these crops are valued for the dry matter they contain, which varies from 8 to 9 p.c. in turnips to 15 p.c. in mangolds and 25 p.c. in sugar beet. About two-thirds of the dry matter exists in the form of readily assimilated sugar.

**Foetus** (Lat., offspring). Biological term meaning the young of an animal, usually with reference to a visible embryo either in an egg or within the womb. The term is applied to that stage of the development of the embryo after its various parts can be distinguished up to the period of birth. See Embryology.

## FOG: OBSCURITY IN THE ATMOSPHERE

A. J. Drummond, F.R.Met.S., and David Le Roi

*An explanation of the causes, nature, and varieties of fog is followed by a description of fog signals; also of methods of air navigation in fog and of fog dispersal*

Obscurity in the surface layers of the atmosphere due to the condensation of water vapour as surface clouds, or to smoke held in suspension in the air, constitutes fog. Meteorologically, the term is limited to conditions when objects as near as one km. are not visible. In country districts fogs result purely through condensation, in industrial areas smoky atmospheres produce the well-known yellowish-black fogs, and in desert regions dust fogs occur. High fogs, where condensation takes place one or two thousand feet above

the surface in a layer containing a great amount of smoke, are observed over large cities, particularly London. In such instances it may be as black as night overhead without significant reduction in the horizontal visibility.

Radiation fogs, formed by the cooling of the surface layers of air below the dew point, although generally of short duration may be extremely dense, especially in river valleys and grassy hollows. When the sun's heat is sufficiently powerful this type of fog thins out rapidly. Another kind of fog forms

when warm air flows over cold ground, or when mixing of two currents of air at different temperatures occur. Thus, off Newfoundland, the warm air over the Gulf Stream produces dense fogs when it meets the cold air over the Labrador Current. Land fogs are formed mostly during winter months; sea fogs are characteristic of spring and summer. Although the upper boundaries of fogs are often not sharply defined and may continue upwards as clouds, the height is usually less than 1,000 ft. Mist is fog in a lesser degree.

**NAVIGATION IN FOG.** Fog signals of the type used at sea and on board ship are purely warning devices, not intended to enable shipping to continue under way; in crowded waterways shipping normally stops in heavy fog. There are, however, devices to allow ships to navigate in bad visibility. Many large liners are equipped with a cathode-ray oscillograph. Vessels moving in a fog area automatically transmit every 15 secs. on a wavelength of 600 metres short signals lasting approximately 1/100th of a second; these signals are picked up by all similarly equipped ships and appear as lines on the oscillograph screen. According to the direction of the lines on the screen protractor, it is possible for the receiving vessels to establish the relative course and bearings of all transmitting ships within range.

Another device is the fog camera, developed during the First Great War. Fitted to the ship's bridge, this camera automatically takes photographs every minute by infra-red rays which penetrate fog and smoke. The films are automatically developed and fixed in 50 secs., and by pressing a button at the side of the camera the officer of the watch instantly illuminates the latest negative. The camera has disclosed objects 6 m. distant when visibility was virtually nil. It is not so effective at night, when it will pick up only such objects as ships, lighthouses, and buoys equipped with apparatus for transmitting infra-red ray beams.

Radio beacons and direction finding are described under their appropriate headings. Sonic fog signals are of little use to aircraft, owing to the excessive noise of engine and propeller, but almost all the radio devices used for navigating in bad visibility at sea have been applied to air transport. The *Lorenz Beacon* (*q.v.*) and the

Loran systems have been specially developed.

The increasingly high speed of aircraft, which has steadily reduced the margin of visibility, even in clear weather, has equally steadily increased the risks of navigation in fog, and Feb. 1, 1938, the Air ministry brought into practice a system of one-way "roads" to govern flying in fog. Known as the directional system, it operates when horizontal visibility is less than 1,100 yds., and provides that machines flying in different directions shall fly at different altitudes.

Over the area covered by air routes between Great Britain and the Continent, the whole air space above 19,000 ft. is reserved for regular liners; while over the rest of England, Scotland, and N. Ireland the scheme operates above an altitude of 3,300 ft. Above that height the air space is divided into four horizontal zones; 3,300-6,600 ft., 7,000-10,600 ft., 11,000-14,600 ft., and 15,000-18,600 ft. The zones are thus separated from one another by a margin of 400 ft., and each zone is divided into 12 layers, in one of which the aircraft must fly during fog according to the magnetic bearing of its pilot's course. (*See Navigation; Radio.*)

**FOG SIGNALS.** Signals of warning to traffic during fogs. The highest development of sonic devices for use when atmospheric conditions obscure normal visual signals has been achieved in the spheres of sea and rail transport. Board of Trade regulations require all vessels at anchor in fog to ring bells at one-minute intervals. Steamships under way sound sirens every minute; sailing ships may use horns or whistles. Audible warning to vessels moving in coastal waters in fog is given either by

bells mounted on buoys, or by fog-horns operated in conjunction with lighthouses.

Modern fog-horns on the coast are mechanically operated, the sonic portion consisting of two cylinders, one of which moves over the other. Both cylinders have a number of perforations which during rotation periodically coincide, so that the upper holes come over the lower ones. When compressed air or steam is forced through the holes of the upper cylinder at the moment when the holes on the lower cylinder coincide, the air is set in rapid vibration. The result is a loud, deep note which is concentrated and sent in the required direction by a large horn or bell-mouthed tube. The moving parts of the fog-horn are driven either by electric motor or by compressed air. The largest fog-horn of this type is at the Cumbrae lighthouse in the Firth of Clyde, which in favourable circumstances can be heard for 20 miles. The Caskets fog-horn consists of mushroom trumpets attached to sirens and blown by compressed air, which distribute the sound all round the horizon. In the U.S.A. attempts have been made to guide shipping by means of eight fog-horns fixed radially, short and long blasts of Morse being sounded according to the compass direction.

The prototype of the coastal fog signal was the bell used in medieval days, as on the Inchcape Rock (*q.v.*). Bell and whistle buoys (*see Buoy*) are still common, particularly for giving warning of shoals, pierheads, and breakwaters. The bells are operated by the movement of the sea, clockwork, or electric motor, and some can be heard for 14 m. On certain lighthouses, such as Eddystone (*q.v.*), use is made of explosive signals detonated electrically at fixed intervals. On the Clyde are unattended acetylene fog-guns which are switched on and off by a radio transmitter on Gourock pier.

Soundless zones are interposed between near and distant audible zones under certain atmospheric conditions. Hence the utility of submarine bells, placed on the sea floor, buoys, and light vessels, and audible to ships fitted with receiving apparatus. The sound can be picked up from 10 m. away. A similar apparatus is sometimes used with submarine cables.

When fog obscures rly. signals, detonators are placed on the line by fogmen stationed at the ordinary visual signals. The detonator consists of two tin cups fitting

Fog-horn on Little Cumbrae island, in the Firth of Clyde; it is operated by compressed air from the cylinders shown

Fog. Automatic railway fog signal, showing engine contact shoe on ramp

tightly together and enclosing a star-shaped piece of lead in which are fixed five percussion caps, the remainder of the space inside the cups being filled with black powder. The detonators are attached to the rail head by lead clips and explode when the wheels of an engine pass over them. In some sections of the line, particularly at stations and junctions, detonator-laying machines are installed; these are operated from the nearest signal box.

Another rly. fog signal, the audible searchlight, works as follows. About a quarter of a mile in front of the "distant" signal a 40-ft. ramp is placed between the rails and connected electrically with a switchboard in the signal box. Beneath the rly. engine is a shoe, which engages with the ramp, closing an electrical circuit. If the distant signal is set at danger when shoe and ramp make contact, a siren sounds in the locomotive cab. At the same time, the electric impulse conveyed through the ramp opens a valve in the vacuum-brake pipe and automatically brings the train to a standstill. If the distant signal is off when shoe and ramp engage, the switchboard in the signal-box rings a bell in the engine, indicating that the line is clear.

Most large signal-boxes are equipped with a train movement and track diagram to facilitate the signalling of trains in fog.

By electric circuits in the permanent way, which are closed by the train's passing over them, a chart of the tracks signalled from the box is illuminated to warn the signalman of all moving and stationary trains.

**FOG DISPERSAL.** Efforts have been made to accelerate by artificial means the condensation of moisture as it comes into contact with the atmospheric particles and so cause fog to fall as rain. Electric precipitation and the sprinkling of electrically charged sand and water from aircraft flying above the fog have been tried, but the clearance is only temporary. In 1938 some success attended experiments conducted by the Massachusetts Institute of Technology. A system of perforated pipes was erected 20 ft. from the ground and sprayed a chemical mixture having the property of dissolving the minute particles of matter constituting fog. At a small aerodrome a dense fog was cleared in five minutes; but dispersal was only temporary. Attempts have been made by the British Association to blow away fog by bombarding the atmosphere with cannon; but the process is unreliable.

Sir Oliver Lodge tried electric dispersal of fog and successfully cleared small areas irrespective of meteorological conditions. Current at a pressure of 400,000 volts was discharged into the atmosphere from a series of high masts.

In 1936 the Air ministry sponsored experiments in dispersal by means of super-heating from radial lamps. The second temperature, or layer of cold air over the warmer, is negated and creates over the aerodrome a pocket of visibility in which aircraft can land. Radial heating has reduced fog up to 40 p.c., but the process is costly.

The high accident rate and the large number of potential flying hours lost through fog early in the Second Great War led to the establishment of the Fog Investigation Dispersal Operation, popularly

Fog. Flames of high pressure "Fido" system burning away fog from the runways of an airfield

known as Fido from its initials. This succeeded in getting rid of fog in bulk by artificial heating of the air. Pipes, through which petrol was pumped at high pressure, enclosed the airfield in a rectangle. At intervals in the pipes burners threw ignited petrol in a flame 2 ft. high.

Initial trials were made in Hampshire on Nov. 4, 1942, when a dense fog was cleared by petrol burners in an area of 200 sq. yds. to a height of 80 ft. The first full-scale test was held at Graveley,

Hunts, a runway 1,300 yds. long by 150 ft. wide being cleared of fog to a height of 100 ft. Fido was used operationally on Nov. 19, 1943, when four Halifax bombers landed in England, after an attack on the Ruhr, in visibility of less than 100 yds. By May, 1945, 2,500 Allied aircraft had been safely brought to ground in thick

Fog. Double fog detonators on railway line, operated by the signal above being at "danger"

fog. Rundstedt's Ardennes offensive of Dec., 1944, was halted largely by the weight of Allied air attack by bombers able to take off and land from fog-bound airfields. Fido consumed 70,000 gallons of petrol an hour, and because of its excessive cost was not easily adaptable to civilian use.

**Fogazzaro**, ANTONI (1842-1911). Italian poet and novelist. He was born at Vicenza, March 25, 1842. His first poems, 1863, were followed by a poetic romance, *Miranda*, 1874, and a volume of lyrics, *Valsolda*, 1876, which established his reputation as a poet. These were succeeded by the stories, *Malombra*, 1882, and *Danielle Cortis*, 1885. In 1888 came his first considerable success, the idyllic *Mistero del Poeta*; then the notable trilogy, *Piccolo Mondo Antico*, 1895; *Piccolo Mondo Moderno*, 1901; and *Il Santo* (*The Saint*), 1906; the last of which, his most famous work, was translated into most European languages. A staunch Roman Catholic, Fogazzaro sought to reconcile the theory of evolution with the teaching of his church; he has been described as Italy's modern poet of hope and faith. He died March 7, 1911. A *Life of Fogazzaro* by T. Gallarati-Scotti appeared in 1922.

**Fog-bow**. Rainbow of about 40° in arc with a broad white band in place of the more usual middle green-blue. The outer edge appears reddish and the inner faintly violet. It is observed during foggy weather, hence the name. The white band results from overlapping of the refraction colours, due to the smallness of the water drops present in fog. See *Rainbow*.

**Fog Crystal**. Phenomenon observable during fog and frost. Fog crystals are usually formed by particles of ice on surfaces in a fog, in frosty weather, as the fog is driven over those surfaces. These crystals, most common in hilly districts, are feathery in appearance, often reach several feet in thickness, and form with great rapidity in favourable conditions.

**Foggia**. A province of S.E. Italy, formerly known as *Capitanata*. In Apulia, bounded N. and E. by the Adriatic Sea, it has an area of 2,683 sq. m. Mountainous in the N.E. and W., it has in the central part a fertile plain. The coast is low and flat, and the climate hot and dry. There are numerous rivers, the chief of which is the *Candelaro*, with many tributaries. The lakes of *Lesina* and *Varano* lie in the N. of the

prov., and the *Lake di Salpi* in the S.E. The highest point is *Monte Calvo*, 3,460 ft. Vast flocks of sheep are pastured on the plain. Pop. 504,449. *Pron.* Foj-ya.

**Foggia**. City of Italy, capital of the prov. of Foggia. It stands in the centre of the Apulian plain, 78 m. E.N.E. of Naples, and 20 m. S.W. of Manfredonia, a junction of the coast rly. and the lines to Benevento and Potenza. The 12th century Gothic cathedral was partly destroyed by an earthquake in 1731, and rebuilt. An important fair is held every May for the sale of sheep, wool, corn, capers, and cheese. An ancient city, Foggia was a favourite residence of the emperor Frederick II, whose English wife, the daughter of King John, died here. Three miles N. of the city are traces of the ancient town of Arpi, or Argyripa, reputed to have been founded by the great hero, Diomedes. Pop. 62,340.

During the Second Great War, Foggia became important as a centre of air activity. With its 13 airfields, it was captured from the Germans on Sept. 27, 1943, by a mobile column of the British 8th army. It became the base of the U.S.A. 15th A.F., which raided S. German, Austrian, Hungarian, and N. Italian targets from here.

**Fogo** (Port., fire). Volcanic island of the Cape Verde archipelago. Circular in shape, and mountainous in character, it has an area of about 190 sq. m. The loftiest point, the *Pico do Lano*, nearly 10,000 ft., has often been in eruption, notably in 1847, when it caused immense damage. Fertile in the N., where coffee, sugar, maize, and fruit are produced, Fogo is almost barren in the S. The chief town and port is *São Filipe*, or *Nostra Senhora do Luz*—*Our Lady of Light*.

There is another island of this name off the N.E. coast of Newfoundland in lat. 49° 40' N. and long. 54° 10' W.

**Föhn** (Ger.). The warm dry southerly wind which blows down the leeward slopes of Alpine valleys. The rise necessary to cross the ranges dynamically cools the air, producing rainfall in the mountains. On descending the other side the air, which has lost considerable moisture, is heated by compression and thus reaches the villages as a warm, drying wind. One explanation for the descent of the warm air into valleys already filled with cold air is that the latter is removed by mixing due to turbulence.

Another reason put forward is that the cold air gradually drains away, drawing the warm air downwards into the valley.

This wind in a few hours clears away more snow than many days of bright sunshine, and uncovers the upland pastures. In some valleys the early sowings are entirely dependent upon this wind, whilst in others it is relied upon to ripen the grapes in autumn. Strictly the term should not be used of a wind, but merely of the effect of descent upon a wind. The föhn effect can be recognized in most mountainous areas in temperate latitudes. See *Wind*.

**Föhr**. Island in the North Sea, one of the N. Frisian group, belonging to Germany. It lies off the W. coast of Slesvig, opposite *Dagebüll* on the mainland, and has an area of 32 sq. m. Largely marshland, protected in the N. by dykes, it is elsewhere elevated and timbered, with fertile soil. The inhabitants live by wild-fowling, fishing, and catering for visitors. The chief town is *Wyk*, a resort on the E. coast. Pop. 7,000.

**Foie-gras** (Fr., fat liver). Livers of geese enlarged abnormally by keeping the birds in a heated compartment, and made into the paste known as *pâté de foie-gras*. The *Strasbourg* variety is well known.

**Foil**. Weapon used in fencing. It is a very slender, four-sided steel blade, with a handguard to the hilt, and a button on the tip, the object of the fencer being to touch some part of his opponent's body with that button. See *Fencing*.

**Foil**. In metallurgy, a thin form of metal, which may be said to occupy a position intermediate between a leaf, e.g. gold leaf, and sheet metal. A very thin tinfoil is made for chemical and electrical uses, and for backing mirrors; tinsel is a rather thicker foil much used for theatrical purposes; Dutch foil is specially prepared for the backing of artificial gems, to give brilliance; it is coloured by Prussian blue and other pig-

Foil, fencing weapon, and method of holding

ments. Gold foil has been used by dentists for stopping teeth.

Ordinary commercial tinfoil, largely used for wrapping tobacco, chocolates, other sweets, and toilet articles, is made of lead coated on one or both sides with tin, the two metals being rolled together so that they become quite inseparable. The tin surface may have merely an infinitesimal thickness, yet it is sufficient to prevent contact with lead. The latter metal contributes the substance and the flexibility to the foil; the tin, much the more expensive metal, provides the non-poisonous surface.

Aluminium, with its light weight, makes a thin foil as an alternative to that of lead. A beautiful variegated foil, which we owe to the Japanese, is made by soldering together by their edges 30 or 40 thin sheets of gold, silver, copper, and various alloys; punching or cutting a pattern through these sheets, the holes going to varying depths, then rolling down the "book" of sheets to the desired thinness. The holes disappear in the finished product.

**Foix.** Town of France, capital of the dept. of Ariège. It stands between the rivers Ariège and Arget, 46 m. S. of Toulouse. Its interest is mainly historical, as the capital of the county of Foix. The powerful counts of Foix lived in its castle, of which there are some remains on the rock, round which the older part of the town clusters. The church of S. Volusien dates from the 14th century. There are small industries, and the town is the commercial and administrative centre for a large district. The county of Foix varied in extent from time to time. It was ruled by its counts, vassals of the king of France, and was one of the provs. into which France was divided before the depts. were created. Pop. 6,806. *Pron.* Fwah.

**Fokine, MIKHAIL** (1880-1942). Russian dancer and choreographer. He was born in St. Petersburg (Leningrad) and began his studies as a dancer under Karsavina's father at the imperial school of ballet. He developed his ideas for the reform of conventional ballet, and a meeting with Benois and Diaghilev (*q.v.*) proved eventful, for during the famous season of Russian ballet in Paris in 1909 he produced *Les Sylphides*, *Le Pavillon d'Armide*, *Cléopâtre*, and *Prince Igor*. Among his later ballets were *L'Oiseau de Feu*, *Scheherazade*, *Le Spectre de la Rose*, *Le Coq d'Or*, *Petrouchka* (considered his masterpiece), and

Paganini. For Pavlova he devised *Le Cygne*. He died in New York, Aug. 23, 1942. *See* Ballet; *consult also* M. F. and his Ballets, C. W. Beaumont, 1935.

**Fokker, ANTHONY HERMAN GERARD** (1890-1939). A Dutch aeronautical engineer. He was born at Kediri, Java, April 6, 1890, and educated at Haarlem, starting his aeronautical career at 20. Fokker became well known after his success in a competition for military aircraft at St. Petersburg. Before the First Great War his designs had been offered unsuccessfully to the British and Italian governments. They were accepted by Germany, and his first biplanes and triplanes gained a great reputation, especially after they had been fitted with an interruptor gear that permitted a machine-gun to be fired through the propeller. After the war he established aircraft factories in the Netherlands, Spain, and New Jersey. Fokker went to the U.S.A., where he died Dec. 23, 1939. His autobiography, *Flying Dutchman*, was published in 1931. *See* Controlled Gun; also *Aeroplane illus.* p. 134.

**Fold.** In geology, the warping or bending of strata which were originally deposited in more or less horizontal layers. Folds are caused by earth movements and are usually associated with compressional stresses acting in the crust. A step-like inclination of strata in one direction is referred to as a monocline. The up-arching or down-warping of beds produces anticlines or synclines respectively. These are elongated, like folds formed in a pushed tablecloth, normal to the direction of greatest compression, and in their simplest form can be likened to a sheet of corrugated iron.

Individual folds tend to die out along their lengths; hence their crests or troughs are rarely horizontal. Such folds which have a slope along their lengths are said to pitch or plunge. Intense compression of the beds leads to the asymmetrical development of folds in which one limb is steeper than the other. The folds are then inclined, and with further movement may be pushed further over to

become overturned or even recumbent. Where a fold has been so squeezed that its limbs are more or less parallel it is isoclinal. Dome- and basin-shaped fold structures can be formed as well as the more common elongated types. The outward dip of strata around a dome is termed *quaquaversal*; the inward dip around a basin is *centroclinal*. Folds are of the greatest importance in the economic applications of geology. The formation of slate is usually associated with folding. Artesian water supply is often obtained from synclines, as in the broad basin-like structure of the Chalk below London.

Oil concentrations are commonly located at or near the crests of domes or anticlines.

**Folding Machine.** A machine primarily in use in printing to convert into sections the flat sheet of printed paper as it comes from the press. Before its adoption these flat sheets were folded by hand. Each class of machine varies in its action, but generally the folded sheets are automatically fed up to a side-gauge on the machine bed, and then brought to the correct position by an automatic device to ensure accurate folding. A descend-

Fold : in geology. 1. Monocline. 2. Upright anticline (A) and syncline (S) with vertical axial planes (ap). 3. Pitching folds, anticline (A) and syncline (S); direction of pitch (P) shown by arrows. 4. Tightly compressed folds becoming almost isoclinal

ing blade then presses the sheet between two revolving rollers through which the sheet passes, thus making the first fold. The sheet then travels to the second pair of rollers, set at right angles to the first pair, where a similar action is performed, and so on for each succeeding fold.

Some machines are made for parallel folding, i.e. folding the sheet over and over in the same direction by blades and rollers parallel with each other operating consecutively. Imagine the first fold down the centre of one way of the sheet and the second fold parallel with the first; we then have the

sheet the original length one way, and one-fourth the original length the other way; a third parallel fold is then made, and as this enters the delivery it is slit into sections by slitting disks. Thus a book of 144 pages, of the page size of this one, would consist of 9 sections of 16 pages folded in the manner last described, 2 sheets each 40 ins. by 54 ins. being converted into 4 sections 10 ins. by 6½ ins. This

Folding machine. Double sixteen book-folding machine, constructed to fold a sheet into two lots of 16 pages, one lot inserted in the other, to make a section of 32 pages

principle of parallel folding is adapted to printing machines producing magazines.

In all the latest styles of folding machines the sheets are fed in automatically, and in some instances sheets are supplied from piles, folded, gathered, stabbed, and the covers glued on before delivery. The uninitiated have probably been puzzled as to the reason of letters in the bottom margin of a book; these are identification marks, and indicate the sections in which the book is folded, thus, the first page of the first section of 16 pp. or 32 pp. will be marked A and the first page of the second section B and so on. These letters enable the sections to be collected in sequence instead of by pagination.

Newspapers are folded by means of an auxiliary part of the printing press. The endless web of paper travels over a V-shaped plate, forming the first fold or spine of the newspaper; the web continues its course (now in page size) until it reaches another section of the machine, the next fold being then accomplished by means of a turning blade attached to and rotating in a cylinder. There are many types of folding machines for the making of boxes and cartons, notepaper folding, etc.

**Foliation.** In geology, a structure characteristic of metamorphic rocks, particularly of schists. It consists of the arrangement of the rock-material in more or less parallel, sometimes lenticular, and frequently undulating layers. Split-

ting usually takes place readily along these layers. See Rock.

**Foligno** (anc. *Fulginium*). City of Italy, in the prov. of Perugia. It stands in a beautiful valley, on the river Topino, 23 m. by rly. S.E. of Perugia, and is enclosed by medieval walls. It has a 12th century cathedral, which has been modernised, several old palaces, and a picture gallery. There is trade in paper, leather, parchment, silk, and soap. An ancient city, Foligno was razed to the ground in the wars of the 13th century. Rebuilt, it was greatly damaged by earthquakes in 1831 and 1832. The cathedral and a palace were damaged and an oratory destroyed by bombs in the Second Great War. The town was entered by Allied troops, June 16, 1944, the Germans having already withdrawn.

**Folio** (Lat. *folium*, leaf). In bibliography, a book of the largest size, the sheets of which are folded once into two leaves, making four pages. For convenience in binding, two or more sheets are inserted into each other. In all but modern books the watermark of the paper is seen in the centre of the page if the work is a folio; if in the middle of the inner margin, divided by the fold at the back of the book, with the chain lines horizontal, the book is a quarto (*q.v.*).

The word folio is applied to the numerical mark on each page of a printed work or each leaf of MS. It is used to indicate the number of words in a page of law writing, or report of parliamentary proceedings, to a case for holding music, and, in book-keeping, to the two facing pages of a ledger or account book containing respectively the creditor and debtor accounts. In 16th century English the word was used to mean "on a large scale." See Book; Paper, Sizes of.

**Folk Dance.** Term for any form of dance native to a people. Originating in religious custom and ritual ceremony, the native dance has continued as a folk dance among peoples long after the religious significance has died out. Many European folk dances are still linked with the old seasonal festivals of pre-Christian days. European folk dances may be roughly divided into two types: (1) ceremonial and ritual dances,

with magical purpose behind the ritual, which were performed by a select group of initiated men, and which retain their ceremonial character and their link with an old seasonal festival; (2) dances performed by the community as a whole, which gave rise to the various forms of social dance which have been the recreation of the people throughout history.

Ceremonial dances, often of a dramatic nature, symbolise fertility, the contest of life and death, and the rebirth of nature in spring. Fertility dances include the English morris or morrice; the Robin Hood games; the Staffordshire horn dance; the hobby horses; and these have their counterpart in Continental folk customs. Contest dances are performed by two opposing lines of dancers, dressed to show their difference in kind: the whites and the blacks, the reds and the blues, the uglies and the beautifuls. Rebirth dances are represented in England by the Northumbrian and Yorkshire variants of the sword dance, which is part of a popular drama, the folk play or mummer's play, with death and resurrection as the central theme. Common to all three forms of ceremonial dance is the practice of actors disguising themselves by masking or blacking their faces.

#### English Folk Dances

Social folk dances no doubt sprang from a festival of general celebration which followed the completion of the ritual dances. Many of the English kind are derived from the early forms of maypole round; others from processional ceremonies, such as the furry dance of Helston. From the old rounds and long dances have grown other types of set dance, including the square of four couples. During three centuries a continual process of exchange of social dances between town and country has exercised influence on the style and manner of dancing. The true folk dance has always been characterised by a natural simplicity and a spontaneous gaiety. Lancers, quadrilles, etc., popular in the ballroom fifty years ago and imported into England from France, are not true folk dances but town versions of the older rustic square folk dance. Examples survive as true folk dances in country places in England and are widespread in America. English country dances that have been popular in town life have been preserved in printed collections since the Stuart days,

and it is therefore possible to follow their evolution to recent times.

The folk dance in Europe was in danger of dying out with the passing of the peasantry. Societies and organizations were founded in many countries to preserve and revive the folk dances as part of the national tradition.

The music of the folk dance is simple, melodious, and strongly rhythmic. The characteristic instruments used are the whistle, or pipe, and drum. In England this familiar combination, played by one man, was known as the whittle and dub, or pipe and tabor (*pron. tabber*). It is still found in association with the men's morris dances, but mostly it has been supplanted by the fiddle, and more recently by melodeon and accordion. The actual folk tunes used for dancing are variants of folk songs and popular songs of any time, modified by the musician to suit the particular dance. The country dance tunes used for social purposes in town life were of no great musical merit. *See Dancing.*

Douglas Kennedy

**Folkestone.** Mun. bor., watering-place, and Kent, England. It stands on the English Channel, 71 m. by rly. S.E. of London. For its holiday visitors the many attractions include the Leas—a fine promenade of nearly 2 m. on the W. cliff, commanding a splendid view from 100 ft. high of the sea—Kingsnorth Gardens, and Radnor Park, a public pleasure ground. There are tennis courts, golf links, bowling green, and a racecourse. The bathing is good to the E. of the harbour. Between Folkestone and Dover is a

Folkestone seal

large open space called the Warren, an extensive landslide, in which fossils are found.

Folkestone consists of an old town in a valley, now the fishing and shipping quarter, and a newer town on the hills around. The chief church is dedicated to S. Mary and S. Eanswith; it is Early English, with a fine tower, much restored. There are also modern churches and several fine hotels. The town has several good schools, a public library, and a museum. As a seaport Folkestone has been much improved during the 20th century, both harbour and pier having been enlarged. It is one of the chief sailing ports for France (Boulogne).

Folkestone was in existence before the Norman Conquest. It became, and still is, a member of the Cinque port of Dover, and was early a corporate town. There was a monastery here from about 1095 until the time of Henry VIII, and also a castle. Heavy damage was caused by German air raids in

1940. The council still derives a considerable income from the coal dues collected in the port. There are memorials to William Harvey, discoverer of the circulation of the blood, who was born here. Near is Shorncliffe camp. Much of the land belongs to the earl of Radnor, whose eldest son is Viscount Folkestone. With Hythe, Folkestone elects one M.P. Pop. 41,240.

**Folkland.** Name given in England in Anglo-Saxon times to the land that was held by folk or common right and subject to certain established burdens. Until 1893 the prevailing idea was that it was the common land of the nation, as opposed to bocland, which was in the nature of private property; but in that year Prof. Vinogradoff established the modern theory. This assumed that practically all the land of the country was folkland, although the king could by grant convert it into bocland. *Consult Domesday Book and Beyond, F. W. Maitland, 1897.*

## FOLKLORE: ITS ORIGINS AND STUDY

E. S. Hartland, Author of *The Science of Fairy Tales*

*There are in this work articles on the various characters in folklore, among them Fairy; Genie; Roc; Valkyrie; Witch. See also Legend; Mythology*

The term folklore was suggested by W. J. Thoms, the antiquary, in 1846, to replace the more cumbersome title of popular antiquities, hitherto employed for the traditional tales, songs and sayings, customs and superstitions of the peasantry. On the foundation in 1878 of The Folk-Lore Society, it was adopted and incorporated into the name of the society. But researches and inquiries have compelled a broader view. All the evidence went to show that the traditional customs and institutions, songs, tales, and amusements, beliefs, leechcraft, and so forth of the peasantry in

civilized countries are survivals of an indefinite past, and for the most part bear the impress of a far ruder age; they present innumerable analogies to those of modern savages; resemble them in the one essential feature that they are traditional; and may reasonably be supposed to be ultimately derived from a social condition represented by many tribes which are still living in a low state of culture.

Accordingly in the second edition of *The Handbook of Folk Lore*, issued by the society in 1914, the definition adopted for the term folklore was "the generic term under which the traditional beliefs, customs, stories, songs and sayings current among backward peoples, or retained by the uncultured classes of more advanced peoples, are comprehended and included." The same term is used for the scientific study of these objects; and folklore as a science may be more succinctly and exactly defined as the study of tradition.

To quote the handbook again: "Folklore is the expression of the psychology of early man, whether in the fields of philosophy, religion, science and medicine, in social organization and ceremonial, or in the more strictly intellectual regions of history, poetry, and other

Folkestone. The cliff-top promenade known as the Leas, a feature of this Kent resort and port.

Photo, Lambert Weston, Folkestone

literature." It thus embraces the whole outlook of uncultured man upon the world, his beliefs concerning his own nature and destiny, his relation to other beings, whether objective or imaginary, whether human or non-human, the rites and customs which are the outcome of his beliefs and the expression of these varied relations, and, finally, the amusements of his vacant hours.

The English use of the word *folklore* does not include, as the corresponding German word *Volkskunde* does, the technology of the arts and industries practised either by the unlearned classes of civilized peoples or by the uncivilized or semi-civilized peoples of distant regions. The English student of folklore is concerned rather with the non-technical rules which govern the employment of implements, and with the ceremonies and taboos observed in relation to them, for these reveal the deeper thoughts of the community and the direction of its mental and spiritual life.

#### Old Devonshire Customs

Folklore may be said to be the deposit left by successive waves of culture on the minds of the community. The record is usually far too fragmentary to present anything like a history. What is preserved is that which—whether tale, institution, rite, or custom—has most deeply entered into the popular mentality. At the village of Holne, on Dartmoor, on May-morning before daybreak a ram-lamb used to be hunted down by the young men, fastened to a monolith, killed, and roasted whole. At mid-day a struggle took place for a slice of the animal, which was supposed to confer luck for the ensuing year on the fortunate person who ate it.

At King's Teignton, on Whit-Monday, a lamb is drawn about the parish in a cart covered with garlands. On the following day it is killed and roasted whole in the middle of the village; and slices are sold to the poor at a cheap rate. The custom is said to date back to heathen days, and to owe its origin to a drought, in which the inhabitants prayed for water. Their wants were supplied in answer to the prayer by the bursting forth of a spring, which even now is adequate in a dry summer to work three mills. The sacrifice of the lamb is said to be a votive thank-offering (Sir Laurence Gomme, *Ethnology in Folklore*, 1892).

In these two Devonshire customs it is impossible to avoid recognizing a survival from very ancient times of a sacrificial ceremony. It is a striking and picturesque rite; but from our point of view this is by no means essen-

tial to its preservation. Thousands of traditional observances are of a common-place character, some even disgusting; and it is difficult to say what quality in them caused them to survive. The prohibition, for luck, to put both shoe and stocking on one foot before the stocking is put on the other, has no striking or picturesque features, but the importance it attaches to a trifling detail in the order of dressing indicates that it descends from so remote a past that the original reason seems undiscoverable.

The belief that it is a bad omen if a child do not cry at its baptism, the prohibition in Scotland to give fire out of the house on New Year's Day, and many other precepts and beliefs obviously derive their origin from a much lower stage of culture. Of such survivals it may very often be said, in Sir Arthur Mitchell's words, that "they show the continuance among a people long Christianised of ceremonies and practices emphatically pagan." Where they cannot be said to be "emphatically pagan" they are alien in spirit from modern thought.

From time to time it has been sought to disentangle and classify such survivals, so as to show the ethnic elements of which they are composed. Thus, Sir Laurence Gomme argued that the sacrifice of the lamb in Devonshire was an inheritance from a pre-Aryan society and a pre-Aryan culture. W. H. R. Rivers instituted an elaborate inquiry into the different strata of the institutions and customs obtaining in the Melanesian islands of the South Pacific (*History of Melanesian Society*, 2 vols., 1914). He arrived at some very interesting results, but the questions raised are so complex, the influences are so numerous and varied, and many of them so hypothetical, that it cannot be said that the possibility of assigning the different elements of folklore to their original ethnic source has anywhere yet been demonstrated.

#### Folklore and the Historian

The value of folklore as a record of facts and of the succession of events is much more limited. Ancient historians—for instance, Herodotus—necessarily relied to a great extent on tradition. All through the Middle Ages, and even more recently, it was treated as authoritative. Modern historians have become more sceptical; and the untrustworthiness of oral tradition, in comparison with the more certain evidence of written documents or the statements of eye-witnesses, has been generally regarded as axiomatic.

In the lower zones of culture, however, documentary evidence of events long past is, of course, unobtainable. The evidence of tradition is the only direct evidence possible. In these circumstances some anthropologists have been disposed to rely on it for such matters as the origin and migrations of a people, the pedigree of its chiefs and rulers, the beginnings of its institutions, and the vicissitudes of its history.

#### Subjects of Tradition

Careful examination shows that this reliance is hardly justified. Illiterate persons certainly develop a greater strength of memory than those who habitually depend on books and written memoranda. But both individuals and communities differ widely in this respect: all are not gifted alike. Much depends, also, on the subject. Pedigrees may be remembered because they appeal to the vanity of a family, or because they are important in relation to the descent of property, or the headship of a clan. The interest thus aroused tends to preserve tradition. On the other hand it almost inevitably deforms it. Whether it be material prosperity, or only pride in the doings of ancestors, or the position of a family, what is sure to be insisted on is the glory and advantage of the carriers of the tradition, and the depreciation or the misdoings of their opponents; and where there is no precise record, there is no conclusive answer to their claims. These are, in a sense, private traditions.

Where a tradition is not so closely related to the interest of the individual, or of a close corporation, it is liable to become less definite, the details will be speedily forgotten, and though outstanding facts will continue to be longer remembered, they will remain isolated and unexplained. Ultimately they will pass out of memory, unless an effort to explain and account for them be made. For this explanation the imagination must be drawn on. Without any real historical sense, the story can only be reconstituted as the carriers of the tradition think it ought to have been, in accordance with their ignorance, their mental condition, and their consequent sense of the fitness of things. The result is a mere travesty of the facts, and oftentimes, indeed, is a complete reversal of them.

It might be thought that bare lists of kings or genealogies would be easily remembered by the aid of a fair memory, and would lend themselves but little to freaks of

imagination. In practice this is not so. Apart from the constant occurrence at the head of such lists of eponymous heroes whose former existence is a mere postulate to account for the name of a tribe or clan, a single example of the untrustworthiness of genealogies may be taken from the pedigrees of the chiefs of various sections of the great Thonga tribe in South Africa. It by no means follows that the names given in these pedigrees represent successive steps in the genealogy.

A step may be omitted because in the native mind for this purpose the distinction between a son and a grandson is immaterial. Steps may be duplicated, because a brother may have succeeded a brother in the chieftainship. Or a longer gap may intervene between two names represented as those of father and son. All these errors and others occur in the pedigrees in question, and the native depositories of tradition do not agree among themselves on the subject. The lists do not affect to contain the names of more than eight or ten generations, going back at the most from 200 to 250 years. Yet a Portuguese document dated in 1554 already mentions several of the names, some of which were then probably the names of clans rather than of persons, and two of them are in the document expressly stated to be the names of rivers (Junod, *Life of a South African Tribe*, i, 24-26).

#### A Typical Legend

A legend very widespread in England and other parts of the W. of Europe concerns the position of a church. It asserts that the church, generally a parish church, was intended to be built elsewhere than on its actual site, but that the materials and the building so far as erected were nightly removed by invisible powers, and that the builders were ultimately compelled to accept the site thus supernaturally chosen.

Two examples, both taken from Gloucestershire, will show how tradition may disguise, and in one case entirely reverse, the facts. The story of Bisley church is that it was to have been built in a certain spot definitely pointed out, but the stones were removed at night by the devil to its present site. Actually, the place pointed out as the intended site was the site of a Roman villa, from the ruins of which the materials for the church, or some of them, were obtained. When the church was restored in the 19th century, portions of the villa, including an altar of the Penates, were found embedded in

the walls (Gloucestershire N. & Q., i, 390). Of Churchdown church, a few miles away, on the top of an isolated hill, the tradition recorded is that it was begun "on a more convenient and accessible spot of ground, but that the materials used in the day were constantly taken away at night and carried to the top of the hill, which was considered as a supernatural intimation that the church should be built there."

The fact is that the hill-top was fortified probably from prehistoric times (the rampart is still to be seen), and the original village was there with its church, but that some time before 1170, doubtless in consequence of the greater security of the country, the village—but not the church—was removed down to the side of the hill, and the top subsequently became deserted. The tradition, now comparatively old, could not have originated until the history of the village had been forgotten.

#### Vagueness of Tradition

It may be said in general terms that the exact facts cannot be recovered from tradition after a century, or at most two. Subsequent to that they become vague, confused, and at length fade out of recollection. In France memory hardly goes beyond the Revolution. It is "a sort of chronological landmark, the only one, beside the reigns of some modern sovereigns and the war of 1870, which the people really knows" (Sébillot, *Folklore de France*, 1904-7, iv, 379). All beyond is vague or forgotten. "Before the Revolution" conveys the utmost antiquity.

Some American Indian traditions go back to the events of the 17th century. They are generally presented under more or less romantic guise, and they cannot be depended on. The Wyandots suffered a very great disaster about the years 1648-50: they were massacred, and the tribe was almost totally extinguished by the Iroquois. It might be supposed that so terrible an experience would have been deeply impressed on the minds of the people. So far, however, is this from being the case that "practically nothing seems to have been remembered" (Barbeau, *Huron and Wyandot Mythology*, 1915).

Instances like those cited might be multiplied indefinitely. They render it impossible to rely upon folklore to transmit a knowledge of events. What it does transmit is a record of the mentality of past generations and of earlier stages of civilization. Such a record is transmitted not merely by tale and song and saying, but

also—and perhaps still better—by game, institution, periodical observances, and the more intimate doings and cautions of daily and family life, as well as by the shapes taken by the beliefs in the supernatural and the uncanny. The problem for students of folklore is to unravel them, to compare them with familiar phenomena elsewhere, and to assign to each of them its place and meaning in human evolution. *Consult Handbook of Folk Lore*, C. S. Burne, 2nd ed. 1914; *Introduction to Folklore*, S. J. Brown, 1933.

**Folk-Lore Society.** British society formed with the object of collecting and preserving the relics of folklore. It was founded in 1878, and publishes a quarterly journal, *Folk Lore*, and also occasional volumes and periodical Transactions. It meets at the Royal Anthropological Institute, 21, Bedford Sq., London, W.C.1.

**Folk-moot.** Name given to a moot or meeting of the folk or people. There were moots of various kinds in medieval times, e.g. the shire-moot. Theoretically all freemen could attend, but practically nothing is known of the matter except that among the Teutonic tribes there were meetings of this kind. In England, according to one theory, there was a folk-moot in each of the little kingdoms until these were united and the witan became the dominant assembly. *See Moot; Witenagemot; consult Primitive Folk-moots*, G. L. Gomme, 1880.

**Folk-Song.** Song created by the common people, those whose cultural development has been effected, not by any formal system of training or education, but through the unconscious and intuitive exercise of natural and inborn faculties. Albeit folk-music is the creation of unlettered and technically unskilled musicians, it is not on that account embryonic, i.e. undeveloped or inferior music. The difference between the music of the people and that of cultivated musicians is one of kind, not of degree, akin rather to the difference between the wild and the garden flower—neither of which can be said to be incomplete or imperfect.

Folk-music ordinarily consists of melody only; it is very seldom—e.g. among the peasants of Great Russia—that it has been carried as far as the harmonic stage. Technically, the folk-tune is essentially non-harmonic in construction and implication, being devised by those in whom the harmonic sense is dormant. It is frequently cast in one or other of the diatonic modes more rarely of the chromatic,

and occasionally in the major, but never in the minor mode; and it is free in its rhythm, metrically irregular, often in five-time and other compound measures. Aesthetically, the characteristic of the folk-tune is its transparent sincerity, freshness, spontaneity, naïveté, and directness of statement.

These considerations, coupled with the fact that folk-tunes are invariably anonymous, have led to speculative theories concerning their derivation. Some experts maintain that folk-songs, like other songs, were composed in the past by individuals, and have been handed down more or less incorrectly by oral tradition, i.e. that the folk-song is not a genuine wild flower, but merely a garden escape. Others contend that folk-songs are the creation, not of individuals, but of homogeneous groups or communities; that the process of oral tradition has been responsible, not only for their preservation, but for the course of their development, and, in a sense, for their actual creation; that the alterations unconsciously made by individual singers have at every stage of the evolution of the folk-song been weighed and tested by the community and accepted or rejected by their verdict; and that the life-history of the folk-song has, therefore, been one of continuous growth ever approximating to a form congenial to the taste of the community and expressive of its feelings, aspirations, and ideals.

The weakness of the individualistic theory is that it fails to account not only for the anonymity of the folk-song, but also for its distinctive national flavour, which is, perhaps, the most characteristic and most valuable of its many peculiar qualities. It is because folk-song is pre-eminently a national utterance that its preservation is essential to the musical well-being of the nation of which it is the natural musical expression. No nation has suffered more than England through the failure to realize the necessity of maintaining a close connexion between its folk and its art music, as may be seen by contrasting the foremost position which the country held in musical Europe prior to Purcell, with the humble place to which it has since been relegated.

Fortunately for the future history of English music, the efforts that have been made since the beginning of the century to collect and record its popular music have been attended with a success far greater than, in the circumstances, could have been expected. In this all-important work the

English Folk Song Society, founded in 1898, has played a leading part, having already recorded in its *Journal* several thousand authentic folk-songs. In addition, several selections of harmonised folk-songs have been published by musicians and collectors, e.g. Lucy Broadwood, Ralph Vaughan Williams, George Butterworth, and Cecil Sharp.

Cecil J. Sharp

**Follen, KARL** (1795-1840). German poet. Born at Ramrod, Hesse, Sept. 5, 1795, he was son of a lawyer. He was educated at the university of Giessen and became a teacher of law, but his revolutionary ideas made it necessary for him to betake himself to Switzerland and then to the U.S.A. He became a professor of German at Harvard and later a Unitarian minister at Lexington. In Jan., 1840, he lost his life when on a burning steamer. He is known by his patriotic songs. His brother, August Ludwig Follen (1794-1855), was also a poet.

**Follicle** (Lat. *folliculus*, little bag). In anatomy, a minute gland or sac such as the hair-follicles of the skin. In botany, a dry dehiscent seed case, consisting of one carpel, which opens along the ventral suture.

**Follies, THE**. Pierrot troupe which achieved popularity in London, especially at the Apollo Theatre, and to a limited extent in the provinces, between 1907 and 1912. The Follies owed their success largely to the personality of H. G. Pélissier (d. 1913), who was their moving spirit and composed for them such songs as *My Moon*, and *The Toothbrush and the Sponge*, as well as writing sketches. Potted Plays, a series of burlesques of contemporary productions, were a feature.

**Follow-on**. A term used in cricket. When the side which takes its innings second makes a score of 150 or more runs below that of the opponents, it may be required to bat again immediately. Thus the captain of the leading team is relieved of having to decide when to close his second innings had he taken it, and may gain victory without batting again.

**Folly**. Name given generally to a building for which there appears to be no particular use or reason. The term is of twofold origin and derives from both the French word *folie*—meaning a pleasance, a delight, or a whimsical phantasy, and as a rule applied to garden-pavilions, belvederes, or look-out towers—and from a castle built in the Welsh marches by Hubert de

Burgh. He had scarce completed it when, under the terms of a treaty with the Welsh, he was obliged to demolish the fortress. This futility was styled "Hubert's Folly."

A typical instance of what the rustic calls a folly is the Folly Gate of Brookmans Park, near Hatfield, an embattled red-brick structure of imposing design, thought to have been erected by Sir Jeremy Sambrooke in the 18th century. "Roebuck's Folly" in the grounds of Midford Park, near Bath, is said to have been built in 1700 to commemorate the winning of a fortune by the ace of clubs. The Farmers' Folly, a pillar erected at Alnwick in 1816 by the tenants of the duke of Northumberland, to testify to their appreciation of him, was completed by the duke at his own expense. Sham Castle, or "Allen's Folly," overlooking Bath, was built in 1760 by Ralph Allen. The palatial building erected at Font-hill, Wiltshire, by the author of *Vathek*, is sometimes referred to as Beckford's Folly.

**Folquet of Marseilles** (c. 1150-1231). Provençal troubadour. He was the son of a merchant from Genoa settled at Marscellos. His few surviving poems show his amorous and passionate disposition; his verses won him the admiring friendship of distinguished men and gained him a place in Dante's *Paradiso* (Book ix). He became abbot of Le Toronet, Provence, in 1198, and seven years later was made bishop of Toulouse. With Simon de Montfort he fanatically persecuted the Albigenses.

**Fomalhaut** (Arab. *fum al hūt*, mouth of the fish). Star Alpha in the constellation of Piscis Australis, the southern fish. It is a star of the first magnitude, and one of the four ancient royal stars. It can be seen low down towards the south in Great Britain in Sept. *Pron.* Fō-ma-lō.

**Fomentation** (Lat. *fovere*, to warm). Fold of lint or similar material, wrung out in boiling water and applied to relieve pain or inflammation, or to encourage the discharge of pus. It should be covered with jaconette, or oil silk, and cotton wool, in order to retain the heat as long as possible, and should be renewed every 3-4 hours.

**Fomorian** (Goidelic, sea-people, or giants). Legendary name of an early Irish race. They are claimed by some as Gaelic spirits of darkness and the sea, by others as an echo of the Viking age. -Archaeology, however, points to early arrivals of Nordic "giants" from the Hebrides, and of early voyagers from the Mediterranean.

**Fonblanque**, ALBANY (1793-1872). British journalist. Son of a banker of French descent, he was born in London, and educated at Woolwich, intending to adopt a military career. At 20 he gained success as contributor to *The Morning Chronicle* and *The Times*. He succeeded Leigh Hunt as principal leader writer to *The Examiner*, of which journal he was proprietor until 1847. His intellectual radicalism and caustic wit exerted considerable influence in the political field, and in 1837 his articles were republished under the title *England under Seven Administrations*. He died Oct. 13, 1872. A second edition of his leading articles was published in 1874.

**Fond du Lac**. City of Wisconsin, U.S.A., the co. seat of Fond du Lac co. At the head of Lake Winnebago, 59 m. N.N.W. of Milwaukee, it is served by several rlys. It contains rly. repair shops, and is a shipping point for dairy and agricultural products and lumber. Manufactures include machinery, wagons, refrigerators, furniture, leather, and shirts. A Capuchin monastery is near by. Settled about 1836, it received a city charter in 1852. Pop. 27,209.

**Fondi** (anc. *Fundi*). City of Italy, in the prov. of Littoria. On the Appian Way, 11 m. N.E. of Terracina, it is enclosed by crumbling walls. Among its buildings are a cathedral, and a Dominican convent in which Thomas Aquinas dwelt. Fundi was a Volscian town of some importance. It came under the sway of the popes in the 8th century, and suffered at the hands of Barbarossa in 1534. Fondi lies in a fertile district, and in ancient times was celebrated for its wine. Pop. 11,378.

**Fonsagrada** (Sp., sacred fountain). Town of Spain, in the prov. of Lugo. It stands on the slopes of the Cantabrian Mts., at an alt. of 3,166 ft., 26 m. N.E. of Lugo. It is a mart for local agricultural produce, and carries on flour-milling and the manufacture of frieze and linen. Pop. 19,219.

**Fonseca**. Gulf or arm of the Pacific Ocean. It penetrates inland to a depth of 40 m. between Honduras, Salvador, and Nicaragua. Two volcanoes—Conchagua and Coseguina—stand on either side of its entrance, which is 21 m. wide. On the small island of Tigre in the gulf is the port of Amapali, a name by which the gulf is sometimes called.

**Fonseca**, MANOEL DEODORO DA (1827-92). First president of Brazil. Born at Alagoas, Brazil,

Manoel da Fonseca.  
Brazilian president

Aug. 5, 1827, he joined the army in 1849. He was engaged, 1864-70, in the fighting against Montevideo and Paraguay, and rose to the rank of general. Though sympathetic with the republican party he was a personal friend of the emperor, Dom Pedro, and was, 1886, appointed governor of the province of Rio Grande do Sul. Becoming more closely identified with the republican movement, he was recalled: he headed the insurrection which was followed by the establishment of the republic of Brazil. He was appointed its first president in Feb., 1891, but resigned in Nov. He died on Aug. 23, 1892.

**Font** (Lat. *fons*, stem *font-*, fountain). In eccles. architecture, the basin for the rite of baptism. Constructed of either marble, stone, or lead, it was placed in a part of the church reserved for the pur-

pose, or in a separate baptistery. Since total immersion was customary in the early Christian baptism, fonts were of considerable size. Gothic fonts were often covered by a lid of elaborate construction. The church of Notre Dame at Hal, Belgium, retains a font with a heavy brass cover of this type, which is removable by a crane attached to the wall.

Norman fonts are square or round, with massive pedestals, and are often ornamented with sculptured figures or other decoration; there were few sculptured fonts before this period, the Saxon examples being mostly plain tub-shaped structures made, in the early stages, of wood. A few pre-Norman fonts, however, are rudely sculptured. During the Gothic period fonts followed the line of general architectural development. Thus the pedestals in the 13th century are often made up of clustered shafts. Most of the extant font covers in Great Britain belong to the 17th century, but a few very beautiful covers were added to existing fonts during the

Giovanni, Siena. 4. Marble font, 1546, and bronze cover with statue of S. John Baptist by F. Segala, 1568, S. Mark's, Venice.

Georgian era. Such is the canopy to the 13th century font at Beverley Minster, which is fashioned in the Renaissance manner with cherub heads and other ornament.

**Fontainebleau.** Town and commune of France, in the dept of Seine-et-Marne. Lying 37 m S.E. of Paris on the Paris-Lyons rly., and about 1½ m. from the left bank of the Seine, it is famed chiefly for its palace and for the forest of Fontainebleau which surrounds it. The town has manufactures of porcelain and gloves paving-stone quarries, and grows a fine type of dessert grapes. A favourite Parisian resort during the summer season, it has an important school of military engineering and artillery. Pop. 15,008

The palace of Fontainebleau was founded probably by Robert II of France about 998, and rebuilt by Louis VII. His building was demolished by Francis I, who built a new palace on the same site, which was in turn expanded and ornamented by almost each successive monarch, and became the favourite dwelling-place of Napoleon I. It was also much altered and decorated by Louis Philippe between 1837-40. It remains one of the finest buildings in France, no less for its internal than its external and garden beauty. There are four principal courts forming the main structure: the Cour du Cheval Blanc, Cour de la Fontaine, Cour Ovale, Cour d'Henri IV. The staircase of Louis XIII, the gallery of Francis I, the banqueting hall, and many paintings and tapestries are notable. The palace has seen many historic events, including the signature of the revocation of the edict of Nantes, 1685, and the abdication of Napoleon I, 1814.

The forest, which is a state property, has an area of some 42,500 acres, and a circumference of nearly 57 m. Its beautiful mixed woods, covering broken and often rugged ground, have attracted many artists to the smaller vil-

lages in and near them, notably to Barbizon (*q.v.*). It suffered severely from fires in 1895 and 1911

**Fontainebleau Sandstone.** Division of the Oligocene system of rocks developed near Paris. It is notable on account of the remarkable purity of the sands, which are composed almost entirely of water-clear quartz, with high silica-content (over 99.65 p.c.), and of great value in glass-making.

**Fontaine Notre Dame.** Village of France, in the dept. of Nord. It is on the Bapaume-Cambrai road, 2½ m. W. of Cambrai. Captured on Nov. 21, 1917, by the British in the first battle of Cambrai, it was recaptured by the Germans in their counter-attack, and finally regained by the British in Sept., 1918. See Cambrai, Battles of.

**Fontana, DOMENICO** (1543-1607). Italian architect. Born at Mili, Lake Como, he studied at Rome, where he obtained the patronage of Cardinal Montalto (Pope Sixtus V), becoming pontifical architect under him in 1585. His works included the Lateran Palace, the N. transept of S. John Lateran, Rome, and the lantern of the main dome of S. Peter's (according to Michelangelo's design). After Sixtus's death, 1590, he became royal architect at Naples, where he built the Palazzo Reale, and where he died.

**Fontane, THEODOR** (1819-98). German novelist and poet. He was born at Neu Ruppin, Brandenburg, Dec. 30, 1819. He first attracted notice by his romantic ballads; later, as novelist, he was known as an uncompromising realist. Some of Fontane's more notable stories were *Vor dem Sturm*, 1878; *Stine*, 1890; *Der Stechlin*, 1899; and *Cécile*, 1900. Having visited Britain three times, he wrote *Ein Sommer in London*, 1854, and in 1860 two vols. of letters and sketches concerning England and Scotland. He acted as war corre-

spondent in the Slesvig-Holstein campaign and in the Franco-Prussian War. He published his autobiography in 1898, and died at Berlin, Sept. 20, 1898. *Consult* Theodor Fontane: A Critical Study, K. Hayens, 1920.

**Fontanelles** (Fr., little fountains). Soft spaces present in the skull of the infant. The anterior fontanelle, the largest, is a quadrilateral area occupying the place where later the angles of the two frontal and the two parietal, or side, bones of the head will unite. The posterior fontanelle lies between the posterior angles of the parietals and the occipital bone which forms the back part of the skull. The lateral fontanelles, two on each side, are small and irregular in shape. The anterior fontanelle

does not completely ossify until a year or more after birth; the others close shortly before or after birth. The condition of the fontanelles considered with the age of the child affords indication of health and development to the physician.

**Fontanne**, LYNN (b. 1882). An American actress. Born in London, May 16, 1882, she first

Lynn Fontanne,  
American actress

appeared on the stage in a Drury Lane pantomime, 1909. After a visit to the U.S.A., she played in London in popular pieces until 1916, when she joined Laurette Taylor at Rochester, N.Y., in The Wooing of Eve. Settling in New York, she scored a notable success in 1923 in Sweet Nell of Old Drury, opposite Alfred Lunt (q.v.). The following year she married him, and the partnership of "the Lunts" became world-famous. Their acting was remarkable for its precision, sense of timing, and smooth sophistication. Her memorable performances in London were in The Guardsman, 1924 (filmed 1931); Caprice, 1929; Reunion in Vienna, 1934; Amphitryon 38, 1938; There Shall be No Night, 1943; Love in Idleness, 1944 (renamed O Mistress Mine in New York).

**Font de Gaume**. Palaeolithic cave, 165 yds. long, in Dordogne, France. It contains many mural paintings, monochrome and polychrome, of the Magdalenian period, some of them masterpieces of prehistoric art. The bison, horse, reindeer, mammoth, and rhinoceros are depicted, besides a human face and hands, and designs of huts.

**Fontenoy**, BATTLE OF. Fought May 11 (N.S.), 1745, between the British, Dutch, and some Germans on the one side and the French on the other. The Allies' object was to relieve Fontenoy, a fortified village about 5 m. S.E. of Tournai, Belgium, then besieged by the French.

The French under Marshal Saxe were drawn up across the road from Mons along which, coming from the S., the Allies had to advance. Obstacles had been placed in front, while on their right was the Schelde and the fortified village of Antoin; on their left was the wood of Barri. The Allies under the duke of Cumberland arrived before this strong position, on the 10th, and early on the 11th were

ready for battle. Allied attacks were repulsed, the Dutch in the centre failing to take Fontenoy.

After some delay the British and Hanoverian infantry made their advance. Lord Charles Hay of the Guards greeted the enemy with lively taunts, and the two lines opened fire. At closer quarters the fight was continued, and the cavalry were drawn into it. The British and Hanoverians had closed into a square, but after repelling the first attacks they were at length overwhelmed in the general *mêlée*. More French infantry were brought up; the artillery fire became more intense, and, most vital of all, a brigade of Irish bore down upon the Allies. The square was broken, but they withdrew from the field in good order, although they left behind some of their guns. The losses were about equal, something like 7,000 on each side. The British and their allies had about 45,000 men engaged; the French somewhat more. A monument at the village commemorates the Irish brigade.

**Fontevrault** or FONTEVRAUD (Well of S. Evrault). Town of France, in Maine-et-Loire dept. It is on the Vienne, 10 m. S.E. of Saumur. Here, in 1099, Robert d'Arbrissel (1047-1117) founded a great Benedictine abbey and an order after which it was named. The abbey, which at one time housed 300 nuns and 200 monks under the rule of an abbess, existed down to the time of the Revolution. The church, consecrated by Calixtus II in 1119, contains recumbent statues of Henry II of England and his queen Eleanor of Aquitaine, Richard Cosur de Lion, and Isabella of Angoulême, widow of King John. In 1804 the abbey buildings were converted into a prison. In 1910, when the abbey church was restored, the tombs of Henry II of England, his wife Matilda, and his son Richard I were discovered.

**Fonteyn**, MARGOT (b. 1919). A British dancer. Born at Reigate, Surrey, May 18, 1919, Peggy Hookham was educated at Louisville, Ky., and at Shanghai. She studied under Goncharov, Astafieva, and Ursula Moreton, making her début at Sadler's Wells in 1934 in The Haunted Ballroom. The first ballerina produced by the Vic-Wells co., when Markova left that company she inherited many of her leading rôles. Performances in Giselle, Swan Lake, The Sleeping Princess, Les Sylphides, and A Wedding Bouquet showed the extent of her emotional range.

She had instant success in New York in 1949.

**Fonthill** or FONTHILL GIFFARD. Parish and village near Hindon, Wiltshire, England, 13 m. W.N.W. of Salisbury. William Beckford (q.v.), who settled here in 1796, built Fonthill Abbey at a cost of over £250,000, and disposed of it and the greater part of its contents in 1822 for £330,000. A second Fonthill Abbey was built on the same site by the 2nd marquess of Westminster. The church of Holy Trinity, built 1866, replaced that erected by Beckford in 1748.

**Fonvielle**, WILFRID DE (1824-1914). A French aeronaut and author. Born in Paris, July 24, 1824, he early showed a genius for mathematics, and became a teacher. His opposition to Louis Napoleon during the revolution of 1848 caused his banishment to Algeria after the *coup d'état* of 1851, but he returned at the amnesty (1859), engaged in politics, and studied aeronautics. During the siege of Paris, 1870, he made his escape in a balloon, and went to London, where he gave political lectures. He died April 29, 1914.

**Foochow** or MINHOU. Former treaty port of China, capital of the prov. of Fukien. It stands in a plain surrounded by hills on the river Min, 36 m. from its mouth. The town is enclosed by old and crumbling walls, pierced by seven gateways crowned by towers. The suburbs lie outside the walls, and are almost as extensive as the town itself. The river is spanned by the bridge of Ten Thousand Ages, which is a marvellous example of Chinese engineering; it connects with the island of Nan-tai, the European quarter. The bridge is supposed to be over 800 years old.

Margot Fonteyn. British ballerina, the first produced by the Vic-Wells ballet company

There are shipbuilding yards, an arsenal, a dry dock, numerous wharves, and a school of navigation. The leading industries are connected with cotton goods, timber, tea, paper, matches, spices, cereals, and ores, while there is a large trade with the maritime provinces of China.

Foochow was opened to foreign trade in 1842. In 1941 it was captured by the Japanese on April 21 but recaptured by the Chinese on Sept. 3. The invaders took it again on Oct. 8, 1944, after bitter fighting, and the Chinese regained it on May 18, 1945. Pop. 322,725.

women in China ate powdered reindeer horns long before medicine realized that the need for calcium is doubled in pregnancy and lactation. American Indians knew how to cure scurvy by eating pine needles long before Vitamin C was discovered. Science has provided an explanation for much of this traditional empirical knowledge and cleared it of superstition. The principles have been elucidated and stated in exact terms which enable them to be applied with greater certainty.

## FOOD AND NUTRITION

Lord Boyd-Orr, Director-General, United Nations' Food and Agriculture Organization, 1945-48

*Food and its constituents, their effect on human health and energy, the minimum requirements of the average man: these are some of the facts here explained by one of the world's greatest food experts. See Food Control; Food Preservation; also Fisheries; Flour; Fruit, etc.*

Food is the term applied to substances eaten to sustain life. Nutrition deals with the chemical composition of foodstuffs, the function of their constituents and their adaptation for maintaining health.

The main activities of undomesticated animals are absorbed in the struggle for food. The same is true of man. It is only within comparatively recent times that as many as 15 or 20 p.c. of the world's population have had a reasonable assurance of sufficient food for health. The fight for food has been the main cause for migration of people and the driving force among the masses in great political movements when migration no longer offered prospects of more food. That was true of the French Revolution and also of the Chartist movement in England. After the Napoleonic war the price of bread was so high in proportion to wages that the children of the working classes in the industrial areas had to earn their bread or starve.

### Need for Production

The struggle for food still exists. The land hunger of peasants in eastern Europe and elsewhere is due not so much to a desire to be landlords as to a desire for freedom to retain for their own needs sufficient of what they produce. In Asia lack of food may be the great world political problem of the 20th Century. The population is already more than the land, with primitive methods of cultivation, can support, and it is estimated that by 1970 it will have increased by 400 million, equal to the population of Europe. There will be an explosion of the population unless agriculture and industry are developed to increase home production and imports of food.

A century and a half ago Malthus predicted that growth of the world population would outrun its capacity to produce food. Recently students of population

changes have expressed the same fear. It is estimated, however, that with the scientific knowledge available it would be possible to produce sufficient food for three times the present population of the world. The only absolute limit to food production is the amount of solar energy the earth receives. Only an infinitely small percentage of that is transformed into the food people eat. Where anything grows, food can be produced. The only practical limit to food production is the amount of labour mankind is prepared to devote to it, and the willingness of governments to cooperate in plans on a world scale to apply science to develop the natural resources of the world.

### Food to Maintain Health

The preoccupation with food has developed an instinct which guides both men and animals in the selection of the kind of food needed to maintain health. Where the foods available are deficient in some essential ingredient, this instinct drives animals to seek what is deficient. Cattle grazing on pasture deficient in certain mineral elements eat earth rich in what is lacking. They make long treks periodically to the "salt licks." Pigs kept in confinement on food deficient in lime dig out the lime between the bricks of the pens. This craving for what is deficient in food is called "pica." Human beings show the same instinct. Food taboos and customs among native tribes, which appear irrational to Europeans, in most cases originated from observations of cause and effect. Many of these curious customs foreshadowed discoveries in nutritional science. It has recently been discovered that endemic goitre is associated with a lack of iodine. The Greeks knew that eating sponges and seaweed, which are now known to be rich in iodine, prevented goitre. Pregnant

The science of nutrition which has made such a great advance on traditional knowledge began with Lavoisier, who lived about the time of the French Revolution. His researches proved that the heat needed to maintain body temperature and the energy needed for muscular work were derived from the oxidation of carbon compounds in the body, and that these are supplied by food. He also showed that the amount of oxygen absorbed from the inhaled breath and the amount of  $\text{CO}_2$  given off in the exhaled breath correspond with the total heat and muscular work produced in the body. This discovery of Lavoisier's made it possible to measure the total amount of energy expended by the body under various conditions of external temperature and amount of work done. The next step was to find out how much energy was available in foodstuffs. Liebig, a German chemist who had studied in Paris, took the lead in devising chemical methods for determining the amount of available energy in proteins, fats, and carbohydrates, the three constituents of food which yield energy, and the amount of each in different foods. Biochemistry was developed by the search for such methods of analysis.

### Calorimeter Experiments

In the 19th century, by experiments with the calorimeter, a knowledge of energy requirements of the body was obtained and the chemists worked out the available energy of different foodstuffs. By the end of the century it was possible to determine the amount of food needed for heat and muscular work under different conditions.

As protein is the main constituent of living tissue, it was considered of special importance. It was thought that while fats and carbohydrates could supply heat, it was from protein that the energy for work was obtained. All three constituents can, in fact, yield energy for heat and consequently

for work, and in calculating food requirements they are interchangeable in isodynamic, *i.e.* equal energy-yielding, proportions.

In the beginning of the present century it was assumed that if the diet yielded sufficient calories for heat and energy and contained sufficient protein for growth and replacement of used-up tissues, the needs of the body for food would be met. Diets were therefore calculated in terms of calories and protein, and research on the physiology of nutrition was confined largely to studies of energy exchange and protein metabolism. Dietetics was based on physics and chemistry, which indeed are the logical outcome of the investigations of Lavoisier. His researches were not on the nutrition of the body. They were on the nature of heat and energy. He believed that the body obeyed the same laws of thermodynamics as a machine and used it to demonstrate the principles which replaced the old idea of phlogiston (*q.v.*).

#### Discovery of Vitamins

In the beginning of the present century the physics and chemistry of dietetics began to be supplemented by biological tests. This new line of investigation showed that foodstuffs in their natural condition contained substances now called vitamins which are as important for maintaining life as calories or proteins. It was also found that mineral elements were of greater importance than had been thought. Many commonly occurring diseases, the cause of which had long been a mystery, were found to be due to a deficiency of vitamins or of minerals in the diet. This discovery of the vitamins and the new appreciation of the profound effect of food on health led to a great expansion of research on nutrition to determine the chemical composition of vitamins, how much of each is needed to maintain health, and the amount of vitamins contained in different foodstuffs. In addition to calories and proteins food requirements are now stated in terms of a dozen or more vitamins and minerals.

The constituents of food are usually considered as falling within the following groups: carbohydrates, fats, proteins, minerals, vitamins, and water.

**Carbohydrates** contain only the three elements carbon, hydrogen, and oxygen, the two latter always in the same proportion as in water,  $H_2O$ . There are three kinds of carbohydrates — namely, sugars,

starches, and celluloses. Examples of sugars are glucose  $C_6H_{12}O_6$ , which occurs in fruit juices and also in the blood, and sucrose  $C_{12}H_{22}O_{11}$ , which is found in beet and in sugar cane. Plants such as wheat, rice, and potatoes store their food reserves in the form of starch, and this provides the main part of our carbohydrate supply. Glycogen, or animal starch, is formed from glucose in the liver and muscles of living animals and acts as a reserve store of energy. Cellulose forms the fibrous parts of cereals, fruits, and vegetables. It is not digested by man, but it helps to stimulate the muscles of the intestine.

**Fats** contain the same three elements as do carbohydrates but the proportion of oxygen is much lower. They consist almost entirely of the glyceryl esters of various fatty acids, of which the most commonly occurring are stearic, palmitic, and oleic acids. They contain also what is termed chemically "unsaponifiable matter," which though it constitutes only 1 to 2 per cent of the fat itself, is nevertheless of great nutritional importance, since any vitamins which the fat contains are in this fraction. Fats are present in considerable amounts in animal tissues, and they occur also in many seeds such as cottonseed and linseed. As a source of energy, fat is the most concentrated of all foods.

**Proteins** are essential constituents of all plant and animal cells. They are highly complex compounds of amino acids, more than 20 of which are known to the chemist. The composition and the characteristics of a protein vary according to the nature and the proportion of the amino acids it contains. All the proteins contain nitrogen in addition to carbon, hydrogen, and oxygen, many contain sulphur as well, and some contain phosphorus. While plants can manufacture proteins from inorganic materials (derived from the soil and from the air), animals cannot do this, and must have provided in their diet readymade proteins of plant or animal origin from which they can obtain the amino acids essential for building up their own body tissues. Plant proteins differ from animal proteins both in the number and the proportion of their constituent amino acids. Generally speaking, animal proteins are superior nutritionally to plant proteins, and it is customary to refer to the former as good or first-class proteins, and

the latter as poor or second-class proteins. One protein will, however, supplement another, so that a mixture of animal and plant proteins is biologically more valuable than is either class taken alone.

**Mineral constituents.** In addition to proteins, fats, and carbohydrates, foodstuffs contain various mineral or inorganic constituents. The following are known to be essential for normal nutrition, since they are required for structural purposes and for the physiological functioning of the body: calcium, phosphorus, magnesium, sodium, potassium, chlorine, iron, copper, iodine, and manganese. Many of these mineral constituents are needed only in minute quantities, but they are nevertheless very important for the maintenance of physical well-being.

**Vitamins** are chemical substances present in foodstuffs in very small amounts which are necessary for health but which, with one exception, *viz.* Vitamin D, the human body cannot manufacture for itself. That certain unknown substances were essential for the maintenance of health in addition to the "classical" nutrients, protein, fat, carbohydrates, and minerals, had long been suspected. It was only in the second decade of the present century, however, that their existence was definitely established. As their composition was unknown they were designated by the letters of the alphabet, Vitamins A, B, C, etc. Originally Vitamin B was considered to be a single entity, but it is now known that several different substances are contained in the original Vitamin B. These include Vitamin B<sub>1</sub>, riboflavin, nicotinic acid, and pyridoxin. The chemical structure and properties of many vitamins have now been determined, and it is therefore customary to refer to them as specific substances, *e.g.* Vitamin C as ascorbic acid, Vitamin B<sub>1</sub> as aneurin, etc.

#### Classes of Nutrients

Foodstuffs in their natural state contain these classes of nutrients, together with water, in varying proportions. Animal products, *e.g.* meat, fish, milk, and eggs, are rich in protein and fat, while plant products such as cereals are richer in carbohydrate than in protein. Animal foods contain the fat-soluble Vitamins A and D, while fruits and vegetables contain the water-soluble Vitamin C and Vitamin A, in the form of carotene. Cereals are rich in the B vitamins.

† Present as carotene, and determined biologically.

‡ International units

The table above shows the average composition of some representative foodstuffs.

**DIGESTION.** This is the process of breaking down food into soluble constituents which can be absorbed from the alimentary canal, and is done by ferments or enzymes which are present in juices secreted by glands in the lining of the canal, and in pancreatic juice and bile secreted by the pancreas and the liver, respectively. The pancreatic juice and bile pass into the duodenum by special ducts. The enzymes act as catalytic agents, accelerating the breakdown of the ingested food material, while themselves remaining relatively unchanged. Each enzyme has a specific action affecting only one type of compound, *e.g.* pepsin acts only on protein, lipase only on fat, and amylase on starch.

#### Process of Digestion

The process of digestion begins in the mouth, where the food is broken up by chewing and mixed with the saliva, which is secreted by glands in the mouth. The saliva is slightly alkaline and contains an enzyme (maltase) which breaks down some of the starch in the food into sugar. After mastication the bolus of food is collected on the tongue, which pushes it back into the oesophagus or gullet, while the soft palate is lifted to cut off the passage to the trachea or windpipe. The food passes from the oesophagus to the stomach which acts as a reservoir. Contractions of the muscular wall of the stomach ensure further mixing and mechanical disintegration of the food, which at the same time is mixed with gastric juice secreted by the stomach. This juice contains 0.2 to 0.4 p.c. of hydrochloric acid, and also the enzyme pepsin, which is responsible for the partial breakdown of proteins.

The contractions of the stomach wall pass the food forward to the small intestine and duodenum

through the pyloric valve, a muscular ring at the junction of the stomach and intestine. This valve relaxes from time to time to allow the passage of part of the stomach contents. In the small intestine, rhythmic movements of the walls churn up the food and mix them with the digestive juices, which include pancreatic juice and bile. Further digestion then takes place as the result of the action of enzymes present in these juices. Thus starch is broken down by amylase to glucose, the proteins, already partially digested in the stomach, are split into still simpler compounds by trypsin, and fat, by the action of lipase from the pancreatic juice together with bile, is emulsified and broken down into soluble constituents which can be absorbed into the blood.

Absorption of the digested nutrients takes place mainly through the mucous membrane of the small intestine. The rhythmic movements of the intestine force the unabsorbed food material, and the waste matter excreted from the blood into the gut, into the large intestine. Here water is absorbed by the walls of the gut and the partially dehydrated material passes to the rectum, from which it is excreted from the body through the anus as faeces.

#### Mental Effects on Digestion

The digestive processes are involuntary, but they are affected by the mind. The smell or even the thought of food can produce appetite and cause an outpouring of saliva "making the mouth water." Moreover, the movements of the intestine are affected adversely by emotions of fear, worry, and anger.

**METABOLISM.** In every active living cell a continuous cycle of chemical changes is going on, compounds being built up and broken down, energy being liberated and waste material excreted into the surrounding fluid. These changes are termed metabolism. They de-

pend on the food constituents absorbed from the gut. When these pass into the blood stream soluble carbohydrates (in the form of glucose) and fat may be carried direct to the tissues to be oxidised to yield energy. If, however, there is already sufficient in the blood to meet immediate needs the glucose is converted to glycogen and stored in the liver and muscles, while the fat is stored as such in the fatty and muscular tissue. These stores can be mobilised as sources of energy when required.

#### Surplus Amino Acids

The amino acids are linked in certain proportions and combinations to form the characteristic proteins of the body. As the composition of the proteins in the food is different from that in the body proteins, many amino acids are surplus. The nitrogen of these is split off and converted to urea in the liver and carried by the blood to the kidneys to be excreted in the urine. The remaining part is oxidised in the same way as the carbohydrates or fats to yield energy for work or heat. Minerals in excess of requirement are excreted in the urine or the faeces.

While the effect of a deficiency of one or other of the vitamins is well known, the rôle that they play in the metabolism of the body is not yet fully understood.

**FUNCTIONS OF FOOD.** From food the body derives energy for maintenance of body temperature, muscular work, etc., and constructive material for growth and replacement of wastage of the tissues. Fats and carbohydrates are the chief sources of energy, while protein is the source of material for growth and repair of the soft tissues. Protein in excess of these requirements can, however, be used for the purpose of producing energy.

Of the minerals present in food, calcium and phosphorus are required in large amount, since

they are necessary for the formation of the teeth and the skeleton. Sodium, potassium, and chlorine function in the body in various ways, e.g. by maintaining the osmotic pressure of the body fluids, the acidity or alkalinity of the various digestive juices, and so on. Iron is an essential constituent of haemoglobin, the red pigment of the blood. Traces of copper also are necessary for the formation of this pigment. Iodine is required for the secretion of the thyroid, though only in small amounts, but if these are not available, a serious disturbance of the metabolism occurs. Other minerals, such as manganese, are required in minute quantities and the exact rôle which they play in the body is as yet obscure, but that they are of vital importance is shown by the fact that where they are absent from the diet, the metabolism becomes abnormal and signs of malnutrition appear. As in the case of the enzymes, each of the vitamins has specific functions to perform. When the diet, although adequate in other respects, is lacking in any particular vitamin, the specific functions are not performed, and a disorder, characteristic of this vitamin deficiency, is produced.

#### Vitamins A, B, C, and D

It is known that an adequate supply of Vitamin A is associated with the capacity of the mucous membranes to resist local infections and with the maintenance of a healthy skin. It is also necessary for the formation of the visual purple of the retina, which is required for seeing in a dim light. This vitamin occurs in foods either as the preformed vitamin, or as its precursor carotene, an orange-red pigment which can be converted by the human liver into Vitamin A. This pigment is found in green vegetables, and is particularly abundant in carrots. Vitamin B<sub>1</sub> is concerned with carbohydrate metabolism. In its absence the disease beri-beri occurs, which is characterised by lesions of the nervous system, the cells of which depend on carbohydrate for their energy supply. When the carbohydrate metabolism becomes abnormal as the result of vitamin B<sub>1</sub> deficiency, pathological changes take place in the nerve cells. Vitamin C is essential for the formation of bones and cartilage and for the proper healing of wounds. A deficiency of Vitamin C results in scurvy, a disease

in which there is weakness and pain in the limbs, swelling and bleeding of the gums, and loosening of the teeth. Vitamin D is indispensable for the laying down of calcium and phosphorus in the bones and teeth. When this vitamin is not available either because it is absent from the food or because the body is at the same time deprived of sunlight (which enables it to manufacture its own Vitamin D), rickets develop. In this disease, to which children in particular are subject, the bones, owing to lack of proper calcification, readily become deformed. Such deformities may persist into adult life, with, in some cases, serious consequences to the individual.

**DIETETICS** might be defined as the practical application of the science of nutrition. It deals with the amounts of each food constituent required for health by males and females of different ages and varying activities. The first estimates of food requirements were made by ascertaining what people actually ate. As the science of nutrition developed, requirements were arrived at by experiments in which men were placed in enclosed chambers known as respiration calorimeters. In these experiments the intake of food and oxygen was determined and the energy expenditure of the body, either active or at rest, was measured in terms of the heat produced. Similar information can be obtained by an indirect method, in which the amount of oxygen breathed in and the amount of carbon dioxide breathed out during a given period is determined. By such experimental methods sufficient data have been obtained to estimate with some degree of accuracy the amount of potential energy which must be supplied in the food to meet the requirements of the body for heat and muscular work.

#### The Calorie as the Unit of Energy

The unit used in measuring the potential energy of foods is the calorie, which is the amount of heat required to raise 1,000 gm. of water 1° C. We know from experimental data the amount of heat given out by the different classes of foodstuffs when they are burned. One gram of protein and 1 gm. of carbohydrate each yield approximately 4.1 calories, while 1 gm. of fat yields 9.3 calories. Since the proportions of these constituents in the various foodstuffs are known, the energy

value of a food can readily be calculated. It is evident that foods containing much fat will have a high calorie value, while succulent foods, such as fruit and green vegetables, will supply very little energy.

#### Variation in Calorie Requirements

The calorie requirement of men is as a rule greater than that of women, but the requirement of individuals is dependent on the amount of muscular work which they perform. The following table shows the variation in calorie requirements of men engaged in different types of employment.

<i>Calories per day</i>	
Very heavy work (coal miners, lumbermen)	4,000-6,000
Heavy work (stonemasons, dock workers)	3,500-4,000
Moderately heavy work (carpenters, shoemakers)	3,000-3,500
Sedentary work (clerks, tailors)	2,000-2,500

Though the requirements for various other nutrients cannot yet be estimated with any great degree of accuracy, it is possible from the available evidence to state what amounts of the essential food constituents should be included in practical diets to maintain well-being.

**ECONOMICS OF FOOD.** In the 19th century the food problem in Europe was one of finding sufficient food to satisfy hunger. In England in the early 19th century, the price of a 4-lb. loaf rose as high as 1s. 6d., and wages were very low. After the repeal of the Corn Laws in 1846, cheap wheat came in from the virgin lands of N. America. By the end of the century the price of a 4-lb. loaf was 5d., and wages were almost double what they had been in the early part of the century.

Almost all the working class could obtain sufficient bread and it was thought that the political and economic problem of food was solved. But the discovery of vitamins led to investigations into the adequacy of diets for health. It was found that even in the wealthiest countries, such as the U.S.A. and the U.K., nearly one-third of the population did not enjoy a diet on the health standard. This was due to the fact that foodstuffs rich in proteins, vitamins, and minerals are more expensive than those which are poor in these constituents. Consequently the lower the family income the greater is the proportion of these cheap and less nourishing foods in the diet.

The following list, compiled by G. Morgenstern, shows the cost in pence of 1,000 calories of some common foods in Jan., 1946.

Bread .. .. .	2.0
Margarine .. ..	2.1
Sugar .. .. .	2.3
Potatoes .. .. .	4.1
Butter .. .. .	5.9
Cheese .. .. .	7.0
Beef .. .. .	9.6
Milk (fresh) .. .	12.9
Eggs (fresh) .. .	25.5
Vegetables and fruit ..	40-100

After the world economic crisis of 1929-33, which led to large-scale unemployment with resulting decrease in purchasing power of the working classes, the price of foodstuffs fell below the cost of production, bringing ruin to farmers. In Europe and in N. America, government measures were introduced in an attempt to restrict production and imports in order to raise prices. But at the same time it was known that more than half the world's population suffered ill health due to lack of sufficient food. At the League of Nations assembly in 1935, proposals were put forward for a plan for the "marriage of health and agriculture," i.e. to increase consumption among the badly fed people of the world and so provide a market for all the foodstuffs produced. An international committee of economic, agricultural, and nutrition experts was set up to investigate the food and agricultural problems. This committee made certain recommendations, including the setting up of national committees by each of the governments adhering to the League to investigate the food position. A meeting of representatives of the committees of 20 governments was held in 1938. The outbreak of war in 1939 brought this movement to a close. In 1943, President Roosevelt invited the United Nations to send representatives to a conference at Hot Springs to consider what measures should be taken to bring about freedom from want of food to all men in all lands. A report of the committee led to the setting up of the Food and Agriculture Organization (*q.v.*) of the United Nations.

#### Wartime Fall in Production

During the Second Great War, owing to the fall in food production on the continent of Europe and in certain parts of Asia, and also to difficulty in transport, there was a shortage of food in many countries. The shortage became more acute after the war finished, owing largely to the disastrous

world harvests of 1945. This post-war food crisis in the war-devastated countries was dealt with by Unrra (*q.v.*) and later by the International Food Council set up in 1946 by the Food and Agriculture Organization.

War has always been accompanied by an increased demand for food and followed, as after the First Great War, by decreased demands and a resulting fall in price. Other factors such as good and bad harvests, level of unemployment, etc., also affect prices. In nine of the ten years between 1928 and 1938 the price of wheat in the world market fluctuated by over 70 p.c. This fluctuation in price is the bane of agricultural producers. In recent years several governments have attempted to stabilise prices. But the food and agriculture problem is interlocked with industry, trade, and international finance, and cannot be solved by measures dealing only with food and/or agriculture. The provision of a food and health standard depends as much upon the industrialisation of undeveloped countries, where hunger and malnutrition exist, as upon the development of agriculture. The economic problems of food production and consumption must be studied in the light of these wider issues.

**Food, INSPECTION OF.** Government service in Great Britain, the U.S.A., and other countries maintained to ensure that food supplied to the public reaches defined standards of composition, purity, and soundness. An Act to make the adulteration of bread illegal was passed in Great Britain in 1836, since when a number of Acts dealing either with particular commodities or with food as a whole, as well as sections of general Public Health Acts, have made more stringent the regulations governing the sale of foodstuffs, and extended the powers and duties of authorised inspectors to see that the regulations are carried out.

These various enactments were consolidated in the Food and Drugs Act of 1938 which brought under one comprehensive act all aspects of food and drug inspection, including the treatment of unsound food, precautions to be taken against food poisoning, purity of milk, hygienic condition of dairies, markets and slaughter houses, cold stores, etc. The Ministry of Health is the responsible authority, the minister having power to make and necessary regulations.

In all counties and in the larger towns there are food and drug inspectors, who are sometimes also sanitary inspectors and inspectors of weights and measures. All county councils must, and large towns may, appoint a duly qualified public analyst who must be a highly skilled chemist holding special diplomas such as the fellowship of the Royal Institute of Chemistry in this branch. The inspectors have statutory powers to take samples which they submit to the public analyst, who examines them and issues an appropriate certificate showing whether or not the sample is satisfactory. If it is not, then legal proceedings may be taken against the vendor, the manufacturer, or the distributor according to the circumstances. Other duties of the inspectors include the examination of meat, of slaughter houses, meat markets, etc.; this branch calls for possession of a special diploma. All local authorities have a medical officer of health who is concerned with some aspects of food inspection and may impound food which he has reason to think is likely to cause poisoning.

#### Inspecting Food from Abroad

Under the Food and Drugs Act, port authorities, customs and excise officers, and medical officers of health for the port have to supervise food arriving in Great Britain. Such food is inspected, sampled, and analysed, or examined bacteriologically. In dealing with food, port officials combine three distinct functions: the exclusion of diseased or unsound food, the collection of customs dues on dutiable foods or constituents, and the enforcement of regulations as to composition or purity.

Most civilized countries have pure food laws and systems of inspection much on the same lines as those in Great Britain. In the U.S.A. a Federal Food and Drugs Law has superseded many of the individual state laws; that country has a very thorough system of meat inspection. In the Netherlands and in Switzerland the examination of milk and dairy products is particularly effective, being accomplished largely by regional laboratories so situated that it is possible to bring in all samples quickly—a matter of importance in controlling the bacteriological condition of milk supplies. France has very well developed inspection of meat and slaughter houses, and very numerous detailed regulations for particular foods and wines. Some food exporting countries

inspect food for export carefully, e.g. meat in New Zealand, fruit in South Africa, in order to ensure that food sent abroad attains a required minimum standard.

**H. E. Cox, Ph.D., D.Sc., F.R.I.C.**

**Food, MINISTRY OF.** British government department responsible for controlling and distributing the nation's food. During the First Great War no attempt was made to control food consumption until Dec., 1916, when a food controller was appointed; the main energies of his department were at first devoted to exhortation. The success of the U-boat campaign necessitated sterner measures. Lord Rhondda took office as food controller in the following June. District food offices closed at the end of 1920, the ministry of Food in March, 1921.

A new ministry of Food was formed on Sept. 8, 1939, out of a department which had been operating since 1936. The first minister was W. S. Morrison; Lord Woolton's administration, April 3, 1940, until Nov., 1943, placed the ministry on a sound basis.

The ministry, whose powers were derived from the defence regulations, operated, wherever possible, with or through existing traders, but maintained a network of local offices. Its functions were to ensure adequate supplies of foodstuffs, distribute them equitably, and control prices. In addition to the purchasing and distribution of foods for the general public, the ministry's work included the administration of a welfare food service to expectant mothers and children under 5; regulation of food standards and labelling; and advice to help consumers make the best use of available supplies. *See* Food Control; Rationing.

**Food and Agriculture Organization.** Name of a subsidiary body of the United Nations. Based on plans drawn up at the Hot Springs Conference (*q.v.*) of 1943 on world food supplies and distribution, it was inaugurated at Quebec, Oct., 1945, 42 nations participating, and was the first of the permanent international organizations within the framework of the United Nations to come into existence. The Soviet Union, the Ukraine, White Russia, and Argentina, though represented by observers at the conference, decided not to participate in the organization. Its objects were to procure and coordinate information about agriculture and available food supplies in all member countries, to assist in the fair

distribution of such supplies, and, ultimately, to advise on crops needed, agricultural methods, etc., with a view to securing the best possible standard of nutrition for all the peoples of the world. Sir John Boyd Orr (Lord Boyd-Orr), British expert on nutrition, professor of agriculture at Aberdeen university, was on Oct. 27, 1945, unanimously elected first director-general. The F.A.O.'s second full session, at Copenhagen in Sept., 1946, attended by delegates from 33 of the 42 member nations, set up a committee to study plans for the creation of a world food board (*q.v.*).

**Food and Drugs Act.** Title of several enactments of the British house of commons passed to ensure the maintenance of a prescribed standard of purity, composition, and soundness of food and drugs offered for sale in Great Britain. Earlier legislation of this kind was consolidated in the Food and Drugs Act of 1938. *See* Food, Inspection of.

**Food Chains.** A term used in ecology. Animals eat plants; plants, using the energy of the sunlight, produce food from dead substances. This fundamental difference between plants and animals is the fact round which are built not only the relations between plants and animals, but also between many groups of animals. One kind of animal may, instead of eating plants directly, interpose another kind of animal between itself and the plant. A man eats a sheep which has eaten grass; the relation man-sheep-grass is then a food chain three links long. In the sea extremely long and complicated chains and indeed networks develop involving numbers of kinds of animals.

**Food Control.** Organization of supplies and equitable distribution of essential foods. Food control as currently understood was a product of the First Great War. The Allied blockade forced the German and Austrian governments to organize collection from producers and control distribution, while in Great Britain the loss of E. European supplies and the submarine campaign made it vital to plan imports. Lord Devonport, appointed food controller at Christmas, 1916, was succeeded in the following June by Lord Rhondda. The principles on which he worked were: (1) securing essential bulk supplies, if necessary by government purchasing, e.g. of meat and dairy produce from the dominions; (2)

giving priority of tonnage for essential foods; (3) fixing maximum prices at each stage of selling; (4) eliminating speculators. Given control of supplies and prices at the source, distribution could be left to traders, licensed, and sometimes specifically organized, for the purpose.

#### Control of Supplies and Prices

During the Second Great War nearly every country in the world was forced to adopt some measure of control based on bulk supplies, maximum prices, and a more or less flexible system of rationing. Food control in the U.K., although not complete, for bread and potatoes remained unrationed, was generally considered one of the best worked out and enforced. Thanks to the work of the Food (Defence) Plans department, established in 1936, the machinery was ready to be set in motion when war broke out. When supplies from the Far East had been cut off and shipping lanes lay exposed to attack from Europe, supplies, distribution, prices, and consumption had to be subjected to controls of severity never contemplated before the war.

**Production.** Domestic agriculture was required to yield the maximum for direct human consumption while replacing as far as possible the feeding stuffs, fruit, eggs, etc., which virtually ceased to be imported owing to limited shipping space. County war agricultural executive committees were set up. By price inducements and direct controls, the arable acreage was increased by half, the potato acreage doubled, wheat output trebled, and vegetable production on farms and allotments increased many times. Farmers were encouraged to become self-sufficient in feeding stuffs. Nevertheless, serious reductions occurred in livestock populations, and it was decided that dairy cows should have first claim on available feeding-stuffs. Milk and millable grains were reserved for direct human consumption, and sheep and poultry populations declined by a quarter and the pig population by more than half.

**Imports.** The government took control of imports of staple foods and of all food stocks in the country and in British hands abroad. Control was virtually complete in March, 1940. For all chief foods the ministry of Food became the sole importer. Bulk purchases were made from overseas exporters; exportable surpluses were sometimes purchased in advance.

especially from the colonies. Food missions were established in several countries, while as a member of the Combined Food board, the U.K. helped to plan the allocation of world supplies of scarce foods, itself buying on behalf of the board in certain markets. It was possible to supplement home production with foods economical in shipping space, *e.g.* livestock products, and dried goods.

**DISTRIBUTION.** The government aimed at securing maximum supplies for its controlled channels of distribution, and price structures and marketing systems were devised to this end. Eggs were bought from poultry keepers by licensed packing stations at a higher price than could legally be charged for a retail sale. Farm to farm sale of all grain was prohibited. Fat stock, sheep, and pigs could be sold only to the ministry, while apart from direct off-farm sales, all milk passed via the Milk Marketing board to the ministry. For all important foods, channels of trade were laid down and the ministry assured control by licensing pre-war traders.

#### Allocating Raw Materials

Various methods were used for controlling supplies, transport, and nutritional standards in the food-processing industries. Flour was never state owned although control of the mills fell little short of state management. Sometimes the government owned both the raw materials and the finished products; or it managed the plant direct, as in vegetable dehydration factories. In allocating scarce raw materials like sugar, oils, and fats, the claims of industry had to be balanced against direct consumer demand. For instance, use of millable grains and the composition of national bread were determined by the government in the light of changes in the general grain position. For most foods, retailers registered for supplies on the basis of consumer demand with licensed wholesalers who were mainly established traders. The wholesaler then registered with the first-hand distributor on the basis of his retailers' demand. The country was divided into nineteen divisions and some 1,300 local food control areas, within which retailers' allocations were easily matched with consumer demands, thanks to ration documents and registration.

**PRICES CONTROL.** "Standstill" orders which at the outbreak of war froze the prices of staple foods at their current levels were

soon replaced by specific price orders for individual foods. Price control secured a fair share of food for all consumers, prevented inflation and profiteering. Maximum prices and profit margins were fixed for all stages of distribution. For some agricultural commodities there were also minimum prices to encourage production. Where necessary, the prices of staple foods were kept down by subsidies from the exchequer. By 1943, 95 p.c. of the average household's outlay on food was on controlled commodities.

**CONSUMPTION.** By the end of 1943 essential foods were rationed in specific guaranteed amounts, most other foods on the points and personal points rationing schemes which allowed freedom of choice. Milk, eggs, and oranges were subject to controlled distribution, but potatoes and bread remained unrationed throughout the war, rationing of bread being introduced only on July 21, 1946. Extra allowances were provided for children, expectant and nursing mothers, invalids, and workers unable to use canteens. Supplies to catering establishments were controlled according to the number of meals served, to meet the requirements of floating populations. No ration coupons had to be given up for meals, but these were limited to three courses, with a maximum price of 5s. except in certain restaurants which were allowed to charge in addition a "house charge" varying from a few pence to 2s. 6d. according to their status. The provision of works and school canteens was encouraged, and support was given to local authorities setting up British Restaurants (*q.v.*) for the public.

#### Unfamiliar Foods

Food control brought some innovations for the consumer. To keep up nutritional standards, unfamiliar foods like dried egg and soya flour were distributed. Diet contained higher extraction bread and more vegetables. The advisory and publicity services of the ministry had to explain the necessity for such changes to the public. Vulnerable groups were given priority, even subsidised, in supplies of milk and vitamins. The prescription of minimum standards of composition for many foods and the regulation of labelling and advertising were other aspects of food control.

**Food Preservation.** Methods of keeping food edible beyond the time when decomposition would

take place if it were left untreated. Preservation of food depends on the inhibition of decomposition by bacteria, moulds, and yeasts, collectively termed micro-organisms, of the organic matter composing foods. It is the object of the food preserver so to treat his products that either the micro-organisms are killed or their development is arrested.

Salting and smoking are methods of great antiquity, and are used in particular for meat and fish, which may be packed in salt or, after brining, may also be smoked by exposure to the smoke of smouldering wood. In canning, all putrefactive organisms are destroyed by heat after the food has been enclosed in hermetically sealed containers.

#### Pasteurised Milk

Milk is pasteurised, by two main methods: (1) by the "holder" method it is heated to 138–150° F. and kept at this temperature for 30 minutes; (2) by the high-temperature-short-time process, it is heated for 15–20 seconds to 159.8°–162°F. In both methods the milk is rapidly cooled after heating.

Refrigeration reduces the temperature of food to the point at which no growth of micro-organisms is possible, and as long as this low temperature is maintained, the food will keep. (*See Cold Storage.*)

A recent development of food refrigeration is "quick freezing"; this involves literally the quick freezing, particularly, of fruit and vegetables, as a result of which, when thawed out, they approximate to the quality of the fresh gathered product.

When most of the moisture is removed from a foodstuff (dehydration) and it is thereafter kept dry, micro-organisms have no power to decompose it. Vegetables, particularly potatoes, lend themselves to this treatment. Fruit and fruit pulp can be preserved by sulphur dioxide. Sugar is the preservative in jam (combined with reduction of moisture). Spices have a preservative effect, owing to their essential oil content. Pickles are preserved by brining and fermentation during which lactic acid is produced.

The use of chemical preservatives is prohibited in several countries and limited in Great Britain where, under the regulations of the ministry of Health, the only preservatives allowed are sulphurous acid and benzoic acid.

Preservatives are permitted only in the following food and drinks: sausages, jam, dried fruits, fruit and fruit pulp, beer, cider, fruit juices, alcoholic and non-alcoholic wines and cordials, sweetened mineral waters, crystallised glacé or cured fruit, sugar, cornflour, corn syrup, gelatine, brewed ginger

Fool. The court fool of ancient time attired in his motley  
After A. Lambton

beer, coffee extract, and pickles and sauces made from fruits or vegetables. See Canning; Refrigeration.

**Food Storage.** Biological term for the reservation of food for use later when demand exceeds supply. The process is a biological necessity, induced by the lack of conformity between the variations in availability of food and the need for it. Accumulation outside the organism may be the result of anticipation of events, as in human societies, or of instinctive behaviour, as in storage of honey by bees and nuts by squirrels. Alternatively, food may be deposited within an organism by virtue of the physiological tendencies of its cells; this occurs when excess sugar in photosynthesising cells of plants is converted into assimilation starch. Food storage serves in this instance, and in the conversion of sugar into glycogen in the mammal liver, to level down transitory intermittent maxima of concentrations of soluble food so that the stored material may be reconverted during intervening periods to build up concentration. Food stores may provide for the requirements of an organism during dormancy, e.g. the accumulations in the fat bodies in frogs and

hibernating insects. Reserves are laid down in stems and roots of woody perennial plants and in the rhizomes, tubers, corms, bulbs, etc., of others. They are provided in seeds, eggs, and comparable reproductive structures whenever the individual destined to develop from these is not nourished directly by the parent organism.

**Fool** (Lat. *foliis*, wind-bag). Retainer kept in the medieval period, and up to the 17th century, by kings and nobles for their entertainment. He was licensed in the exercise of his antic buffoonery, his fooling and the shrewdness of his tongue, and is scarcely to be differentiated from the jester. The fool wore a special parti-coloured dress, and a cap shaped like a cock's comb with ass's ears, and carried a mock sceptre with a fool's head carved on it, and a bladder at the end of a string.

**Fools, FEAST OF.** Medieval burlesque religious festival. A survival of the Roman Saturnalia (q.v.), it was originally celebrated on the first day of the year. The Church, although originally opposed to it, eventually allotted special days for its observance. The chief characteristic was at first the inversion of rank. A boy or young man, known by such names as the boy bishop (q.v.) or the abbot of unreason (q.v.), was chosen to conduct the ritual; but the ceremonies quickly degenerated into buffoonery.

The ass, representing Balaam's ass, the ass which stood by the manger, that on which the Virgin and Child fled to Egypt, or that on which Christ rode into Jerusalem, often played a part. In some places there was a special Feast of the Ass, e.g. at Beauvais, where the flight into Egypt was represented by a girl carrying a baby or doll and mounted on an ass, and the priest dismissed the congregation by braying three times, the people responding in the same fashion. The Feast of Fools survived until the Reformation, and as late as 1644 at Antibes in France.

**Foolscap.** Properly, the cap worn by fools and jesters, usually conical in shape with bells fastened to it. It is also the common name for a sheet of paper, strictly 17 ins. by 13½ ins., but frequently smaller. This is so called because it had formerly a fool's cap and bells for its watermark.

**Fool's Parsley** (*Aethusa cynapium*). Annual herb of the family Umbelliferae. It is a native of Europe and Siberia, growing chiefly in cultivated ground. It

has a spindle-shaped root and a smooth stem about 2 ft. high. The large, wedge-shaped leaves are much divided into small, thin segments. The minute white flowers are massed in compound umbels. Though somewhat like parsley, it is considered that its nauseous odour would prevent any but "a fool" from being imposed upon by the resemblance.

Fool's Parsley,  
*Aethusa cynapium*

**Foot.** Lower extremity of the leg on which man stands or walks. The bones fall into three groups: (1) seven forming the tarsus or posterior part of the foot, which correspond to the bones of the wrist; (2) the five metatarsal bones; and (3) the fourteen phalanges, forming the toes. The tarsus consists of the os calcis, which is the largest bone of the foot and forms the heel; the astragalus, which articulates with the tibia and fibula, the two smaller bones of the leg, to form the ankle joint; and five smaller bones—the scaphoid, three cuneiform bones, and the cuboid bone. The metatarsal bones are elongated, and articulate behind with the tarsus and in front with the phalanges.

The phalanges are fourteen in number, three in each of the four outer toes and two in the big toe. The foot is arched in the centre, the posterior pier of the arch being formed by the heel and the anterior by the heads of the metatarsal bones. The dropping of the longitudinal arch produces the condition known as flat foot (q.v.). The dropping of the transverse arch allows the heads of the metatarsal bones to crush the nerves of the

Foot. Diagram showing the bones of the human foot, seen from above and from the side

part, causing intense pain. Treatment is by exercises to strengthen the muscles responsible for the integrity of the arch and by aids placed in the shoe. Club foot or talipes is a deformity which may be present at birth or acquired during later life. In talipes equinus the heel is drawn up and the patient walks on his toes. In talipes calcaneus the toes are raised from the ground. In talipes varus the foot is inverted, the inner side of the foot being raised, and the patient walking mainly on the outer side. In talipes valgus the foot is everted, and the patient walks on the inner side. These deformities may be more or less corrected by massage, manipulation, the use of suitable splints or other apparatus, forcible wrenching, and in some cases operation. In claw foot, or pes cavus, there is an increased concavity in the arch of the foot.

**Foot.** One of the oldest and commonest measures of length, based upon that of a man's foot, traditionally the king's. The English statute foot is divided into 12 ins. In prosody, foot is the term applied to a group of syllables, one of which is stressed to mark the rhythm forming a part of a verse.

**Foot.** Name of a British family of politicians. Isaac (b. 1880) became a solicitor in the Plymouth firm of Foot and Bowden, and 1922-24 represented Bodmin as Liberal M.P., also 1929-35. He was secretary of Mines in the National government, 1931-32, lord mayor of Plymouth 1945-46, and in 1947 became president of the Liberal party organization.

His son, Dingle Mackintosh (b. 1905), was educated at Bembridge school and Balliol College, Oxford, and called to the bar in 1930. He represented Dundee as Liberal M.P., 1931-45, and was parliamentary secretary to the ministry of Economic Warfare, 1940-44. Another son, Michael, born July 23, 1913, was educated at Wadham College, Oxford, and became a journalist, assistant editor of Tribune, 1937-38. Joining the Evening Standard in 1938, he was acting editor in 1942. Under the pseudonym Cassius he wrote political pamphlets. He represented Devonport as Labour M.P. from 1945, joining the Daily Herald staff the same year.

**Foot - and - Mouth Disease.** Fever mainly affecting cattle, sheep, and pigs, though other animals, including man, are also liable. The disease is periodical only in Great Britain, and is then

the result of imported infection. When there is an outbreak, the district in which it appears is isolated by forbidding the movement of cattle, sheep, etc., in or out of it, and the affected animals are liable to be slaughtered, compensation being paid by the government.

It is highly contagious, the virus, which can live for four weeks, being readily carried by soil, hair, or infected milk. In animals the virus gains entrance through the intestinal mucous

membrane, but in man it is more often the result of direct inoculation from the saliva of infected animals, or from milking cows with eruptions on the udders. As a rule adult animals are not fatally affected, but younger animals die. The incubation period is a few days, when a slight fever is accompanied by ulcers in the mouth and on the feet. A weak solution of permanganate of potash is a good local application. See Bacteriology.

## FOOTBALL: ASSOCIATION AND RUGBY

George F. Allison and Major H. B. T. Wakelam

*The two most popular winter games in the United Kingdom, with both players and spectators, are here described and their history told, the one by the former manager of the Arsenal F.C., the other by a well-known writer and radio sports commentator on Rugby*

**ASSOCIATION FOOTBALL.** At the beginning of the 20th century, it was justifiable to refer to Association football as an English game. Forty years later, it was played in nearly every country in the world, taking hold even in America. Instead of showing others how to play, British teams had to struggle grimly against those of other countries.

Football is still an English game, however, in the sense that it had its origin in England. It survived despite royal edicts forbidding the people to play "such an impertinent game." Historians of the 13th century record that "annually on Shrove Tuesday, London schoolboys went into the fields immediately after dinner to play at the celebrated game of ball."

### Forbidden by Law

Its popularity grew, and in 1349 Edward III forbade it by law. Again, in 1359, Richard II passed an Act for the purpose of encouraging shooting, and forbade throughout the kingdom "all playing at tennis, footballe," and various other games. In 1401, Henry IV repeated the embargo. In 1458 James III of Scotland decreed that "footballe and golfe be utterly put down." This football, of course, was not of the organized kind of today—in some matches between rival villages, the goals were two or three miles apart and the contests went on from two o'clock to sunset.

To the schools of Westminster and Charterhouse belongs the major share of the credit for the origin of the rules governing the association code, though other public schools played football in various forms, some of them differing only in minor degree.

The Football Association of England, supreme authority of the game, came into being at a meet-

ing held in London in October 1863. At the beginning of the season 1866-67 only ten clubs were affiliated to it. The first organized football club in England was one formed in Sheffield in 1857; not until 1866 was the first inter-city match played in Battersea park between London and Sheffield.

In 1867 the now famous amateur Scottish club, Queen's Park, Glasgow, was started by a few young enthusiasts. This club built for itself a marvellous arena, Hampden Park, the largest in the British Isles, where the England v. Scotland international match takes place every two years. The attendances at these matches have on occasion neared 150,000.

In 1871 the association passed the following simple resolution: "That a challenge cup be established, open to all clubs belonging to the Football Association." The Association was virtually without funds, and the £25 needed to buy the unpretentious cup was provided by the clubs. Fifteen entered in the first year of the cup competition.

In 1872 the first real international match between U.K. countries was played in Scotland. Within the next few years the game had progressed so much that internationals between England, Scotland, Ireland, and Wales had become established.

Professionalism was officially sanctioned in the year 1885. In 1888 the Football League came into being. At its outset it embraced 12 clubs—Preston North End, Wolverhampton Wanderers, Bolton Wanderers, Aston Villa, West Bromwich Albion, Everton, Derby County, Notts County, Burnley, Stoke, Accrington, and Blackburn Rovers.

There are now approximately 40,000 amateur clubs, and about

three-quarters of a million amateur players affiliated to the Football Association; while there are only about 400 clubs which engage professionals, to the round figure of 5,000. Probably two-thirds are part-time footballers.

Apart from the men who are paid to play, and salaried officials, money cannot be made out of football. The big professional clubs may not be run for personal profit. Some may show a big balance at the end of a successful year, but every penny must go back to the game in some form or another.

#### League and Cup Competitions

In the very first season in which there was both a league and a cup competition, Preston North End carried off both honours, winning the league competition without losing a match, and winning the cup without having a goal scored against it in the competition. It is unlikely that such a dual feat will ever be equalled, though Aston Villa won the cup and the league championship in the same season—in 1895.

The fact that the cup competition was open, at its inception, to any club affiliated to the Football Association accounted for the title Football Association challenge cup. It is now generally referred to as the English cup, despite the fact that Welsh clubs enter in goodly numbers, and that in 1927 the trophy was taken by a Welsh side, Cardiff City.

In the early days of the F.A. cup the final ties were played at Kennington Oval; and in 1876, '77, and '78, it was won by the Wanderers. According to the rule then obtaining, the trophy became the property of triple winners; the Wanderers handed it back to the organizers, however, and it remained as the cup, never to be won outright. But it was stolen from a Birmingham shop window in 1895, while on show after an Aston Villa victory. Nobody, except the thieves, knows what happened to the precious piece of silver. Another cup was provided at a cost of £25, and this remained the trophy until 1909. In that year it was won by Manchester United, whose officials ordered an exact replica for boardroom decoration. The Football Association decided that this was not right. They ordered a new cup, at a cost of £50, copyrighted the design, and handed the previous trophy to Lord Kinaird, first president of the F.A., who had himself been in the winning side five times.

Immediately after the First Great War, finals were played on a club ground—that of Chelsea; but in 1923 Wembley was chosen for the final, and the biggest crowd which has ever assembled for any game turned out to see Bolton Wanderers play West Ham United. The gates of the ground were rushed, and tens of thousands hustled through without paying, to take up positions on the actual playing pitch. That scene brought a new cup final era—admission by ticket only, with the tickets limited to a trifle less than one hundred thousand. It is no unusual thing for cup final ticket applications to number over half a million. (See Association Cup.)

From the original twelve, the Football League gradually grew in numbers, and in 1892 a second division was formed. For a short while promotion from and relegation to this second division was decided by test matches, played at the end of each season, between the lowest pair of the top class and the leading pair of the second class. In due course, however, these test matches were abolished, and promotion for the two top clubs of the second division and relegation for the two lowest clubs in the first division at the end of each season became automatic.

#### League Organization

Football League membership increased to twenty-two per section immediately after the First Great War, and two new sections, southern third and northern third, came into being with automatic promotion and relegation. Starting with 1924, Huddersfield Town won the first division championship in three successive seasons, being the first club to do this. Arsenal equalled this feat in the 1933-34-35 seasons.

Much the same system, so far as promotion and relegation are concerned, was adopted in Scotland, with interruptions from time to time in the relegation and promotion regulations. Scotland also introduced an annual knockout cup competition very much on English lines, and, in 1946, a league cup competition.

On terms arranged between League clubs a player may be transferred from one to another, though no player can be transferred unless he is willing. If he does move, he can be paid only what is called presumed accrued share of the benefit money which he would have received from the transferring club if he had stayed

for the qualifying five-year period. As there are maximum wage rules no player is better off financially so far as direct remuneration for playing the game is concerned, by changing from one club to another.

A player is eligible to play in league games immediately his signing for the club has been registered, but his signing must have been registered for 14 days before a player may play in the F.A. cup competition; and in the latter competition a player is not allowed to play for more than one club in any one season.

#### Transfer Fees

In 1905 Middlesbrough paid the first £1,000 fee to secure the services from Sunderland of Alf Common. From that transaction the fees paid and received for star players went up and up—to £10,890 for David Jack (1928); £14,000 for Bryn Jones (1938); £20,000 for Tommy Lawton (1947); £25,000 for J. Morris, and £26,000 for Eddie Quigley (both 1949). From time to time attempts to limit transfer fees have been made, but a limit of £350 per player made in 1908 did not last even one season. No part of the fee is paid to the footballer himself.

ASSOCIATION RULES. The game is played on a ground marked as shown below. The circumference

Football. Diagram showing lines and dimensions of Association football ground

of the ball must not be more than 28 ins. nor less than 27 ins. The weight at the start of the game must not be more than 16 oz. nor less than 14 oz.

The game is played by two teams, each consisting of not more than 11 players, one of whom is the goalkeeper. One of the other players may change places with the goalkeeper during the match, provided notice be given to the referee before such change is made. Apart from the goalkeeper, a team can be made up

Football. The Association game. 1. Scoring a goal. 2. Breasting. 3. Heading. 4. Dribbling down the wing. 5. Goalkeeper saving a good shot. 6. Over-head clearance. 7. A throw-in. 8. Combination. 9. Punching clear

in any way in the positional sense. A goalkeeper must wear distinctive colours, and no player may wear anything which is dangerous to another player.

The appointed referee must enforce the laws and decide any disputed point. His decision on points of fact connected with the play must be final so far as the result of the game is concerned. His jurisdiction begins from the time he signals the kick-off, and his power of penalising extends to offences committed when play has been temporarily suspended, or when the ball is out of play. He must, however, refrain from penalising in cases where he is satisfied that by doing so he would be giving an advantage to the offending team. Two linesmen should also be appointed, whose duty (subject to the decision of the referee) is to indicate when the

ball is out of play, and which side is entitled to the corner-kick, goal-kick, or throw-in.

The duration of the game is two equal periods of 45 minutes unless otherwise mutually agreed upon, subject to allowances being made in either period for all time lost through accident or other cause, the amount of which is a matter for the discretion of the referee; and that time must be extended to permit of a penalty-kick being taken at or after the expiration of the normal period.

At the beginning of the game, choice of ends and the kick-off is decided by the toss of a coin. The team winning the toss has the option of choice of ends or the kick-off. When re-starting after half-time, ends are changed and the kick-off taken by a player of the opposite team to that of the player who started the game.

The ball is out of play when it has wholly crossed the goal-line or touch-line, whether on the ground or in the air, and when the game has been stopped by the referee. A goal is scored when the whole of the ball has been properly propelled over the goal-line, between the goal-posts and under the cross-bar. The team scoring the greater number of goals during a game is the winner.

A player is off-side if he is nearer his opponents' goal-line than the ball at the moment the ball is played unless: (a) he is in his own half of the field of play; (b) there are two opponents nearer to their own goal-line than he is; (c) the ball last touched an opponent or was last played by him; (d) he receives the ball direct from a goal kick, a corner kick, a throw-in, or when it is dropped by the referee. (It is not an offence for a player to be in an off-side position. He can be off-side only if interfering with the play of an opponent or seeking to gain an advantage.)

#### Rules Relating to Penalties

A player is penalised if he intentionally: (a) kicks, strikes, or jumps at an opponent; (b) trips, including throwing or attempting to throw, an opponent by use of the legs, or by stooping in front or behind him; (c) handles the ball, i.e. carries, strikes, or propels it with the hand or arm (this does not apply to the goalkeeper within his own penalty area).

There are several other offences, some punishable by free kicks from which goals may be scored direct, and others by indirect free kicks, from which goals can be scored only if the ball is touched by a second player. Most offences by defenders, in the penalty area, are punished by the award of a penalty kick, during the taking of which all players, except the kicker and the goalkeeper, must stand outside the penalty area, and outside the arc of the circle. The goalkeeper must stand, not moving his feet, under the cross-bar, until the ball is kicked from the penalty spot. When free kicks are taken all opposing players must stand at least ten yards from the ball, unless they are on their own goal-line between the goal-posts. A player taking a free kick or a corner kick must not play the ball a second time until it has been played by another player.

When the whole of the ball passes over a touch-line, either on the ground or in the air, it is thrown in from the point where it crossed the

line, in any direction, by a player of the team opposite to that of the player who last touched it. If the ball is improperly thrown in, the throw-in shall be taken by a player of the opposing team. When the whole of the ball passes over the goal-line, excluding that portion between the goal-posts, either in the air or on the ground, having last been played by one of the attacking team, it is kicked direct into play beyond the penalty area by a player of the defending team. If the ball is not kicked beyond the penalty area, *i.e.* direct into play, the kick shall be retaken. If a player taking a goal kick plays the ball a second time after it has passed beyond the penalty area, but before it has touched or been played by another player, an indirect free kick is awarded to the opposing team, to be taken from the place where the infringement occurred.

When the whole of the ball passes over the goal-line, excluding that portion between the goal-posts, having last been played by one of the defending team, a member of the attacking team takes a corner kick. A goal may be scored direct from such a kick.

Chapman, 1930; Fifty Years of Football, Sir F. Wall, 1935; Inside Story of Football, G. F. Allison, 1938; Football Ambassador, Eddie Hapgood, 1946.

**RUGBY FOOTBALL.** It is to one William Webb Ellis, a boy at Rugby School, who, in 1823, "first took the ball into his arms and ran," that the beginning of Rugby football is usually credited. Sixteen years later, Albert Pell, an old Rugbeian, introduced the game at Cambridge, where in 1848 a not very successful meeting of interested parties was held in an endeavour to frame a code of rules.

#### Developed by the Schools

Other schools were gradually adopting the Rugby game, notably Marlborough, an offshoot of Rugby, founded in 1843, and Cheltenham, which can claim to be the originator of the numerical scoring system, this being generally adopted in 1886. From the Old Boys' team of the now defunct Blackheath school, the old Blackheathens, there arose, in 1862, the Blackheath R.U.F.C., first acknowledged club in the game. Richmond followed in 1863 (the year of the first Blackheath v.

Football. The Rugby game. 1. Passing on being tackled. 2. Taking a pass. 3. A drop kick. 4. A tackle. 5. Scoring a try. 6. Place kicking. 7. A dash for a try. 8. Making a mark. 9. A scrum

Richmond match), and then came Manchester, Bath, Bradford, Liverpool, Harlequins (known as Hampstead until 1870), Wasps, and other formations. In 1869, Oxford University took up the game, and, in 1870, at Auckland, Rugby first appeared in New Zealand.

On Jan. 26, 1871, a red letter day, Blackheath, Richmond, Wellington College, Guy's Hospital, Harlequins, King's College, S. Paul's, Civil Service, Marlborough Nomads, Queen's House, West Kent, Wimbledon Hornets, Gypsies, Clapham Rovers, Flamingoes, Law, Lausanne, Addison, Mohicans, and Belsize Park met in London to found the Rugby Union. On March 27, 1871, came the first international, at Raeburn Place, Edinburgh, when Scotland beat England by one goal and one try to one try. Teams were then 20 a side—made up of 13 forwards,

three half-backs, one three-quarter and three full-backs.

In 1871-72 Oxford and Cambridge met for the first time, and, in 1873, the Scottish Union was formed, the Irish following in 1879, the Welsh in 1880.

In 1875 it was decided that should no goal be kicked, or should an equal number of goals be kicked by both sides, matches were to be decided by a majority of tries. Previously no match could be won unless a goal was actually kicked, unconverted tries not counting in the reckoning.

In the same year Oxford and Cambridge took the field 15 aside instead of 20, a step which was followed for internationals in 1877, the year of the birth of Rugby in France, and also that of the first Navy-Army match.

Gradually the game became more open and less of a rough-and-

tumble, a big improvement coming in 1881 when three three-quarters were first seen in international matches, but a bigger stride still was due to the Oxford sides of 1881-83 when the art of the half-back passing game was brought out by Alan Rotherham.

In 1885 Paris R.F.C., the first French team to cross the water, appeared against the Civil Service at Dulwich, but more important still was the introduction in the same season by the Cardiff club of the four three-quarter line-up, though this was not generally adopted until 1893-94.

#### First British Visit to Australasia

The first British touring team visited Australasia in 1888, a New Zealand side, known as the Maoris, paying a return visit the same year, and then, in 1890, the International Board was formed. This board nowadays consists of 10 representatives, four from the Rugby Union (never the "English" Rugby Union), and two each from the Scottish, Irish, and Welsh Rugby Unions.

To Rosslyn Park (founded in 1879) goes the honour of being the first club to make an official trip to France—in 1893, when it beat the Stade Français by three goals and three tries to nil.

For some time already there had been discussion concerning the payment of "broken time" to players, who, by force of circumstances, had to sacrifice pay to take off the time to travel to and take part in, matches. The Rugby Union considered the matter at a very long and spirited meeting, but the voting went against payment, the result being the so-called split and the formation of the Northern Union Football League (now the Rugby League), with its 13-a-side teams and its own code of playing laws.

In 1902 Canada sent over her first representatives to the U.K., and in the 1905-06 season came the first meeting of England and France. That season, too, new scoring values were adopted; and a New Zealand team under Dave Gallaher arrived in Britain, shaking up the home players and returning with a record of thirty-two wins against one defeat, and a score of 868 points to 47.

The visit of Paul Roos's South Africans of 1906-07 helped still more, and there followed the Adrian Stoop era in English Rugby. This farsighted genius of the game, first with his own club, the Harlequins, and then with the English fifteen, adopted and im-

proved a new style of play and for some years the Englishmen carried almost everything before them.

More spectacular play meant greater popularity amongst the watching public, and this led to the purchase, in 1907, of the Rugby Union ground at Twickenham, the first match there being played between Harlequins and Richmond on the first Saturday in Oct., 1909. The opening international was England v. Wales in Jan., 1910, England winning by eleven points to six and scoring direct from the kick-off. Stoop caught the ball from this kick and, after a short run, started a movement which finished in the scoring by F. E. Chapman of Westoe of the first Twickenham international try. Twickenham accommodates over 70,000 spectators.

After the 1914-1918 war, came a run of English successes, usually called the W. W. Wakefield era. It was chiefly remarkable for a very highly specialised type of fast and intelligent forward play in conjunction with one of the best pairs of half-backs the game has ever produced, C. A. Kershaw and W. J. A. Davies. C. G. Porter's New Zealanders arrived in 1924 played 30 matches and won them all. The same year the home countries under R. Cove-Smith, visited S. Africa, registering nine wins, nine losses, and three draws.

#### Seven-a-Side at Twickenham

In 1926 another New Zealand team, this time the Maoris, came over to win 22 of their 31 matches. That year, too, was the first in which the seven-a-sides were played at Twickenham. Also the laws of the game were redrafted.

After an Australian touring side, the "Waratahs," led by A. C. Wallace (winning 24, losing five, and drawing two) had paid the home countries a visit in 1927, D. J. MacMyn of Scotland captained a British side to the Argentine. Here they won all of their nine matches, scoring 295 points against nine. Then in 1930 another home touring party, captained by F. D. Prentice, went off to Australasia, winning 20 and losing eight matches.

In 1931-32 came the third South African visit, B. L. Osler captaining a side which relied almost entirely on a fine pack of forwards for its results. It achieved 23 wins and two draws, against only one loss, at Leicester, to the combined Leicester and East Midlands team.

In 1931 occurred the split with France, owing to a difference of

opinion somewhat similar to the 1893 dispute at home. Not until the opening months of the Second Great War was this disagreement finally resolved.

The first official trip to the U.S.A. was made in 1934, W. J. Leather taking over the Cambridge University team, which played four matches and won them all with ease, causing a sensation by speedy running and open methods.

Then in 1935-36 came yet another New Zealand trip to this country, J. E. Manchester leading a side which won 24 matches, drew one, and lost three, going down before Swansea, Wales, and England. To Swansea, the "All Whites," thus went the honour of being the first home club to defeat a New Zealand touring team.

#### The Calcutta Cup

In 1879 the original Calcutta Football club was disbanded, and to mark this occasion it presented a cup to the Rugby Union to be played for annually between England and Scotland, a game generally accepted as the greatest of the year. The famous Barbarian club came into existence in 1890. Since then it has gone from strength to strength, and to be a Barbarian, which can happen only by invitation, is the ambition of every player.

**RUGBY UNION RULES.** The game of Rugby is played between two teams of 15 a side. It is played with an oval ball, 11 to 11½ inches long, 24 to 25½ inches in circumference, and weighing 13½ to 15 ounces. Usually a 15 consist of eight forwards, two half-backs, four three-quarters, and a full-back, the last seven being known as the backs as opposed to the rest, the forwards. The normal line-up is as follows:

#### Full-back.

Right wing three-quarter.  
Right centre three-quarter.  
Left centre three-quarter.  
Left wing three-quarter.

Stand-off (or outside) half.  
Scrum (or inside) half.

- 3 { Flank front row forward.  
Middle front row forward  
("hooker").
- 2 { Flank front row forward.  
Second row forward.
- 3 { Second row forward.  
Outside back row forward  
("winger").
- 3 { Middle back row forward.  
Outside back row forward  
("winger").

This gives the 3-2-3 "pack" of the forwards, though there is quite a common variation, 3-4-1. There is also an outside variation, emanating from New Zealand, in

which the outside half becomes the 1st five-eighth, and one of the centres the 2nd five-eighth, thus leaving only three three-quarters.

The game is played on a ground marked out as shown below, and is controlled by a

Football. Plan of Rugby football ground

referee, assisted by two "touch judges," whose duties include the marking by upraised arm and flag of the places where the ball, or player carrying it, crosses the touch-lines in the course of play. The referee is the sole timekeeper and judge of fact.

#### Duration of Play

Play is divided into two halves of not more than 40 minutes each, with a five-minute interval during which the teams change ends. The start of a game is known as the kick-off, the end as no-side. The run of play depends almost entirely upon the laws of on-side and off-side, a broad interpretation of these laws in Rugby being that a player must never be in front of the ball or of a member of his own side who is carrying it. For in Rugby football the use of both hands and feet is permitted. Including as it does the tackle and the scrummage, as well as open running and inter-passing of the ball from one player to another, it has been described as two kinds of game in one, for it allows for skill, tactics, and speed as well as actual physical contact of the players; and though there is a long and elaborate code of laws, much of the fairness and good feeling of the game depend upon unwritten law, and therefore upon the honesty and good sportsmanship of the individual player.

The primary object of the game is the scoring of a try, which is obtained when an attacking player first grounds the ball in his opponents' in-goal (*see plan*). This try can then be converted into a placed goal if any player in the attacking team kicks the ball by a so-called place kick over the opponents' cross-bar without its touching the ground or any player of either team. A goal is scored if the ball has crossed the bar, even though it may have been blown back afterwards, and whether it has touched the cross-bar or either goalpost or not. It is also a goal if the ball passes between the imaginary lines of vertical continuation of the goalposts.

#### Scoring Points

Other methods of scoring are the dropped goal, made when a player drop kicks the ball over the cross-bar during the run of play, the goal from a free kick (this is the "mark"), and the penalty goal. Either of these last two can be taken by means of a drop or a place kick. There is also the very rare "penalty try" awarded at the referee's discretion. The following are the point values:

A try	3 points
A goal from a try (in which case the try shall not count)	5 points
A goal from a free kick, or penalty kick (whether placed or dropped)	3 points
A dropped goal otherwise obtained	4 points

A place kick is made by kicking the ball after it has been placed on the ground for that purpose.

A drop kick is made when a player in possession of the ball lets it fall from his hand or hands to the ground, and kicks it at the first rebound as it rises.

A free kick is a kick allowed for a "fair catch."

A penalty kick is a kick awarded to the non-offending team by reason of the infringement of the laws by their opponents.

Both "free" and "penalty" kicks may be taken by place kick, drop kick, or "punt."

A punt is made when a player in possession of the ball lets it fall from his hand or hands, and kicks it before it touches the ground (no kind of a goal can be scored by this means).

A tackle occurs when the holder of the ball in the field of play is held by one or more players of the opposing team so that, while he is so held, there is a moment when he cannot pass or play the ball.

A scrummage, which can take place only in the field of play

(not in-goal) is formed by one or more players from each team closing round the ball when it is on the ground (this is the loose scrum); or by players of each team closing up in readiness to allow the ball to be put on the ground between them, in accordance with the particular law of the game. This is the "set" or "tight" scrum in which the forwards "pack" down in 3-2-3 or other similar formation. It is the method of restarting the game after non-penal offences, and is perhaps the main feature of Rugby football.

A "line-out" restarts the game after the ball has gone into touch.

H. B. T. Wakelam

THE RUGBY LEAGUE (Northern Union from 1895 to 1922) controls the professional game, particularly popular in Yorkshire, Lancashire, and S. Wales. Test matches are played against Australia and New Zealand.

During the Second Great War, League players were allowed to play alongside R.U. amateurs in services matches, but the two codes afterwards separated again, with London seeing League players only once a year—at the R.L. challenge cup final, played since 1929 (with one exception) at Wembley stadium. The league championship resembles that of the Association Football League.

The rules of the Rugby League include the following differences from the amateur game: there are only 13 players a side (including 6 forwards); only 2 points are scored for any kind of goal (in addition to 3 for a try, as in the Rugby Union); a scrummage is taken if the ball crosses the touch-line, a direct kick to touch (except a penalty kick) being followed by a "scrum back" at the spot where it was kicked; the ball must be immediately heeled back after a tackle.

AMERICAN RUGBY, known in the U.S.A. as football, derives from the Rugby Union game. There are 11 players a side, their object being to achieve a touch-down over their opponents' goal-line. The playing field, including end zones, is 360 ft. long and 160 ft. wide; the actual field of play is divided into twenty 5-ft. sections giving rise to the "grid-iron" pattern. The play, both on the attack and on the defensive, is controlled by signals, definite formations being adopted.

*Bibliography.* Rugby Football, H. B. T. Wakelam, 1936; Rugby Football, C. W. Jones, 1937; Rugger's an Attacking Game. P. Lawless, 1946.

**Football Association.** Governing body of English amateur and professional association football. It was founded in 1863 to establish a definite set of rules to govern both Rugby and Association football, but at a preliminary meeting the representatives of the Rugby clubs objected to the proposal to make hacking illegal, and withdrew. The F.A. was formed into a limited liability company in 1903. Its council includes a president, six vice-presidents, hon. treasurer, ten divisional representatives, eight representatives of the Football League, and one of each affiliated association with membership of at least 50 clubs. *See* Association Cup; Football.

**Football League.** Union of Association football clubs for the purpose of playing matches against one another. The main principle is that every club in a league shall play every other club twice during the football season, once at home and once away. The idea was borrowed from the U.S.A., where it was practised by baseball clubs, and was suggested by W. McGregor of Birmingham in 1888. For further details see Football.

**Football Pool.** Competition in which prizes are offered for forecasting correctly the results of League football matches in Great Britain. From 1939 to 1945 the coupons were printed in newspapers and weekly magazines; but since then they have been sent to the client by post. Nearly all promoters offer two types of competition, one involving the selection of a given number of results from a long list of matches, the other all results in a short list. The minimum stake in the former is usually 6d. and the maximum £1. Dividends on this type of pool are calculated by dividing the amount of the stake money, less the promoter's commission and expenses, by the number of correct, or most nearly correct, forecasts.

In the "penny points" pool a forecast has to be made of the results of, say, 12 or 15 matches. Stakes are fixed at a penny per forecast, and winners are determined by the addition of points, one for a home win, two for an away win, three for a draw.

Pools were started in a small way in 1923, but developed rapidly after the Betting and Lotteries Act of 1934 clarified the legal status of off-the-course betting, and some dozen firms formed the Football Pools Promoters' Association. In 1935-36 it was estimated that the average number of weekly sub-

scribers was about 3,800,000, the aggregate stakes received being about £20,000,000. In 1948, total expenditure on football pools by some 10,000,000 subscribers was est. at £61,000,000. A substantial revenue, est. at about £3,000,000 before the betting commission of 1949-50, accrued to the post office, from postage and poundage on postal orders. At Liverpool, the leading English pool centre, the G.P.O. established a special sorting office, inward letters alone amounting to 5,000,000 weekly.

A decision of the court of appeal in 1945 declaring the advertising of football pools in newspapers illegal led to increased personal and postal canvassing. A 10 p.c. duty imposed on stake money Jan. 4, 1948, was doubled in April.

Pools became popular in Sweden, where the government set up a company in 1934 that ran pools on much the same lines as those of the U.K. The biggest prize allowed is £3,700. Most of the profits are used to encourage sport, athletics, and physical training.

**Foot-candle.** In illuminating engineering, the unit of illumination, defined as the illumination, produced by one standard candle at a distance of one foot.

**Foot Drop.** Condition in which the extensor muscles of the toes and the dorsi-flexor muscles of the ankles lose their power owing to poisoning from alcohol, lead, or arsenic, or to shortage of Vitamin B<sub>1</sub>, as in beri-beri. The dropping of the foot necessitates high stepping to clear the ground.

**Footie, SAMUEL (1720-77).** English actor and dramatist. Born at Truro, Jan. 27, 1720 he was edu-

Samuel Foote,  
English dramatist  
After Sir J. Reynolds

called *The Diversions of the Morning*, in which he burlesqued well-known living persons. The magistrates having prohibited its performance, he defied them by issuing a general invitation to his friends to "take a dish of tea with him"—by ticket. With *The Haymarket*, rebuilt by him in 1767, Foote remained connected till 1777, producing there several of his caricature comedies, the best of

which are *Taste*, *The Minor*, *The Orators*, *The Mayor of Garratt*, *The Devil upon Two Sticks*, and *The Capuchin*. He died suddenly at Dover, Oct. 21, 1777, and was buried in Westminster Abbey. His Dramatic Works were edited by M. Belder, 1930.

**Footpath.** Narrow path used by pedestrians over which there is a public right of way. In the U.K. the right has usually arisen from some Act of parliament or from dedication of the land by some owner. Dedication may be by deed but usually will be inferred from long use. If a path has been used for 20 years as of right without interruption dedication will be presumed in the absence of evidence (e.g. notices that a path is not a right of way placed near it by the owner) that there was no such intention, or evidence that no one able to dedicate was in possession of the land. After 40 years, dedication is conclusively presumed in the absence of evidence that there was no such intention. In a rural parish the council may repair all footpaths other than those beside a public road. The National Parks and Access to the Countryside Act, 1949, laid on every co. in England and Wales the duty to survey, and publish maps of, all footpaths and bridleways within its area. *See* Right of Way.

**Footplate.** Metal plate on a locomotive which covers the floor where the driver stands, and extends along both sides of the engine and in front of the boiler. It is also a metal floor-plate secured to the end of a railway corridor carriage, which rests and is free to slide upon the end of the next carriage, to form a gangway. *See* Steam Engine.

**Foot-pound.** Work done when a force of one pound weight moves through a distance of one foot parallel to its line of action. *See* Horse-power.

**Foot Rot.** Term usually applied to a disease affecting the feet of sheep. The animal suffers great pain from an acute inflammation of certain structures of the foot, caused by a microscopic organism which infests low and damp pastures. The disease is readily noticed, for infected animals adopt a kneeling position when grazing.

Affected animals must be removed at once to a dry yard or shed. Dryness is absolutely essential, and if the animals are allowed to stand for a short time daily on a floor covered with slaked lime, the healing process is considerably hastened. Foot rot is highly contagious, and since it takes three

weeks to develop, newly purchased sheep should be kept apart from the rest for 20-30 days.

**Forage.** Name for coarse fodder crops, like straw, as distinguished from green and succulent fodder crops. See Fodder.

**Forain, JEAN LOUIS** (1852-1931). French painter. Born at Reims, Oct. 23, 1852, he studied under Gérôme at the Beaux Arts. After contributing to *Le Monde Parisien*, *Charivari*, *Figaro*, *La Vie Parisienne*, etc., he expressed his satirical talent at its best in *Le Courrier Français* and *Le Rire*, and later in the *Pstt*!, an anti-Dreyfusard sheet founded by himself and Caran d'Ache. He was above all the interpreter and castigator, in exquisite draughtsmanship, of the seamy side of Paris life, of conventions and methods of jurisprudence. Two of his most biting satires, *The Law Courts* and *The Tribunal*, are in the Tate Gallery. After the First Great War he went into retirement and painted still life, but his technique as an engraver gave an element of sharpness to his compositions. He died at La Chesnay, July 11, 1931.

**Foraminifera** (*Lat. foramen*, small hole). Minute creatures belonging to the sub-kingdom Protozoa. Many of them are scarcely visible to the naked eye. Most of them are marine. They secrete a limy or membranous shell, usually perforated with minute holes through which thread-like processes of the body protoplasm can be extruded. With the aid of these pseudopodia (false feet) the animal is able to creep about and to secure the particles of organic matter on which it feeds. The ooze of the ocean beds, and the vast deposits of limestone which form so large a portion of the earth's crust, are largely composed of the dead shells of foraminifera.

**Forbes, ALEXANDER PENROSE** (1817-75). Scottish divine. Born at Edinburgh, June 6, 1817, and educated there and at Glasgow, in 1836 he entered the Indian civil service. His health failing, he returned to England and won a Sanskrit scholarship at Brasenose College, Oxford. Ordained in 1844, he was appointed bishop of Brechin in 1848, but moved the centre of his diocese to Dundee, where he built the pro-cathedral. A prominent high churchman, he was tried in the ecclesiastical courts on a charge of heresy, arising out of the statement of his views on the Eucharist contained in his primary charge, and was censured. He died in Dundee, Oct. 8, 1875.

**Forbes, ARCHIBALD** (1838-1900). British war correspondent. Born in Elginshire (now Morayshire), April 17, 1838, and educated at King's College, Aberdeen, he left the university to enlist in the Royal Dragoons, and, while still a trooper, contributed articles to the papers. In the Franco-

Archibald Forbes,  
British war  
correspondent

Prussian War of 1870-71 he made his reputation as correspondent, first of the *Morning Advertiser* and then of the *Daily News*. He reported on the Russo-Turkish and Zulu Wars, being able in the latter to give Great Britain the first news of the battle of Ulundi, 1879. He wrote *Memories and Studies of War and Peace*, 1895. Died March 30, 1900.

**Forbes, DUNCAN** (1685-1747). Scottish lawyer. Born near Inverness, Nov. 10, 1685, he studied law at Leyden, was admitted advocate and appointed sheriff of Midlothian in 1709, and, for his services in suppressing the rebellion of 1715, was made deputy-advocate. Returned to parliament for the Inverness burghs in 1722, he was appointed Lord advocate in 1725 and lord president of the court of session in 1737. In the rebellion of 1745 he strove hard to keep the rebels in check, but his services were coldly received by the Government. He originated the idea of raising Highland regiments, later adopted by Pitt. He died Dec. 10, 1747.

Cullooden House was his property and in his family for generations

**Forbes, GEORGE WILLIAM** (1869-1947). New Zealand statesman. He was born March 12, 1869, at Lyttelton, and educated at Christchurch. Entering parliament as member for Hurunui in 1908, he held office as minister of agriculture

George W. Forbes.  
New Zealand  
statesman

and of finance before becoming premier in 1930. In the latter post he was also responsible for foreign and native affairs, scientific research, and railways, and from 1933 he was attorney-general. During his five-year premiership Forbes went to the Imperial Conference of 1930 and the World Economic Conference of 1932. His Coalition government was defeated by Labour at the polls, Nov. 27, 1935. He died May 18, 1947.

**Forbes, (JOAN) ROSITA** (b. 1893). British explorer and author. She crossed the Libyan desert in native costume in 1920-21, and reached Kufara, headquarters of the Mahomedan sect of the Senussi, not visited by Europeans since 1879. She made an expedition to Asir, 1922-23, and a journey across Abyssinia, 1924-25. A fellow of the Royal Geographical Society, she described her adventures in travel books and drew on her experience for novels mostly about the East. Her publications include *The Secret of the Sahara-Kufara*; *From Red Sea to Blue Nile*; *Forbidden Road—Kabul to Samarkand*, 1937; *The Prodigious Caribbean*, 1940. Her autobiography appeared in two parts: *Gypsy in the Sun*, 1944; *Appointment with Destiny*, 1946.

**Forbes, DAME KATHERINE JANE TREFUSIS** (b. 1899). British servicewoman, born March 21, 1899. A member of the Woman's Volunteer Reserve, 1916-18, she joined the Council of Emergency Service in 1935 and trained women to serve as officers preparatory to the formation of women's services. She was chief instructor at the A.T.S. school, 1938, and then attached to No. 20 R.A.F. coy., A.T.S. During 1939-43 she was director of the W.A.A.F., with the rank of air chief commandant, and was created D.B.E. in 1944.

Dame Katherine  
Forbes,  
British servicewoman

**Forbes, STANHOPE ALEXANDER** (1857-1947). British painter. Born in Dublin, Nov. 18, 1857, he was educated at Dulwich College, and studied art at the R.A. schools, and with Bonnat in Paris. Influenced by the naturalistic methods of Bonnat, he settled at Newlyn, Cornwall, where he lived until his death. March 2, 1947. It was

chiefly through Forbes that the Newlyn school (*q.v.*) obtained its distinctive character. Elected A.R.A. in 1892, and R.A. in 1910, he devoted his last years to studies of the neighbourhood.

**Forbes-Robertson, Sir John-Ston** (1853-1937). British actor, Born in London, Jan. 16, 1853, eldest son of John Forbes-Robertson, art critic and journalist, and educated at Charterhouse and Rouen, he studied art at the R.A. school, and elocution under Phelps. He

Sir J. Forbes-Robertson, British actor

made his stage debut, March 5, 1874, at The Princess's, London, as Chastelard, in Mary Queen of Scots. In the same year he appeared with Ellen Terry at Astley's. Associated in turns with Charles Calvert, the Bancrofts, Irving, Wilson Barrett, and John Hare, he achieved his first notable success as Geoffrey Wynyard in Dan'l Druce, at The Haymarket, Sept. 11, 1876. His first venture as an actor-manager was at The Lyceum, Sept. 21, 1895, when he appeared as Romeo to the Juliet of Mrs. Patrick Campbell. His farewell season in London was opened at Drury Lane, March 22, 1913, and closed on June 6. In that year he was knighted.

Gifted with a magnetic personality and exceptional elocutionary ability, he was one of the most popular actors of his time. His Hamlet, the Stranger in The Passing of the Third Floor Back, and Dick Helder in The Light That Failed, were memorable. He toured several times in the U.S.A., and in Germany in 1898. His reminiscences, A Player Under Three Reigns, appeared in 1925. He died Nov. 6, 1937.

Sir Johnston's brother, as Norman Forbes (1859-1932), also won distinction as an actor. His sister, Frances, was the author of several novels. His wife, married in 1900, was May Gertrude (born Dec. 14, 1874), sister of Maxine Elliott (*q.v.*), of Oakland, Calif., who, as Gertrude Elliott, made her first appearance on the American stage in 1894, and later won favour as Peggy, in Mice and Men; Ophelia; Desdemona; Portia; Cleopatra, in Caesar and Cleopatra; Maisie, in The Light That Failed; Stasia, in The Passing of the Third Floor Back. Their daughter, Jean Forbes-

Robertson (born March 16, 1905), was outstanding as Peter Pan in several Christmas productions, also in Berkeley Square, and Time and the Conways. She formed her own company in 1934.

**Force** (Lat. *fortis*, strong). Fundamental conception defined by Newton as that which changes or tends to change the motion of a body upon which it acts. Newton's second law of motion states that the rate of change of momentum is proportional to the impressed force, and takes place in the direction in which the force acts. Now momentum is equal to  $mass (m) \times velocity (v)$ , and assuming the mass remains constant the rate of change of momentum is given by  $mass \times rate\ of\ change\ of\ velocity = mass \times acceleration (a)$ . Hence the force ( $f$ ) may be defined by the equation  $f = kma$ , where  $k$  is a constant which is made equal to unity by appropriate choice of units of measurement. In the C.G.S. system the unit of force, the dyne, is that force which produces unit acceleration (one cm. per sec. per sec.) when it acts on a mass of one gram.

The resultant of two forces acting on a body may be obtained by drawing two straight lines, to a definite scale representing the respective magnitudes of the forces, and in the directions in which the forces act on the body. If the parallelogram is completed then the resultant force is given in magnitude and direction by the diagonal drawn from the corner where the two forces act. Force was once regarded as a muscular conception; now it is realized that there are electrical, magnetic, and gravitational forces.

**Forced Loan.** Money taken by kings and other rulers from their subjects by compulsion, but with the promise of repayment, which thus differentiates it from taxation proper. Something of this kind has been done almost as long as society has existed, but in England it first became prominent in the time of Charles I. In 1626 Charles resorted to the device of a forced loan. He dismissed Coke from the chief justiceship for denying its legality, and he punished those who refused to pay by billeting soldiers upon them and in other ways. The question was tested in the courts of law by the Five Knights' Case; in this the judges' decision implied that the king alone could decide whether or not a loan was illegal. To this the parliament replied by the Petition of Right, which declared the exaction of

"any gift, loan, benevolency, or tax without common consent by Act of Parliament to be illegal."

**Force Majeure.** English legal term. A force majeure clause is sometimes inserted in contracts to exempt the parties from liability for loss in certain circumstances. The expression is taken from the Code Napoléon. On the Continent the effect of such a clause is to exclude liability for loss due to circumstances independent of the will of man and not under his control. In England its meaning is not fixed but depends in each case on the nature and general terms of the contract. Alternative expressions, each with a slightly different meaning, are *vis major*, Act of God, inevitable accident.

**Force Ouvrière, LA.** See Confédération Générale du Travail.

**Forceps.** Instrument consisting of two blades for grasping or compressing tissues or objects. The midwifery forceps, used for assisting delivery in difficult labour, is one of the most beneficent instruments ever invented. There is some evidence that forceps of a kind were used in childbirth at Pompeii, and in the 10th century by Arabian physicians. The knowledge was, however, entirely lost, and was rediscovered about the beginning of the 17th century by Peter Chamberlen, a Huguenot refugee, who fled to England. Chamberlen and his sons and grandsons kept the secret in their family for nearly one hundred years, and it was not until 1733 that Chapman published a full description of the midwifery forceps. The word forceps meant an instrument for holding hot iron (Lat. *formus*, hot; *capere*, to grasp). A form of forceps is employed in nearly all surgical operations, and by dentists, watchmakers, etc. See Dentistry illus.

**Forcible Entry.** Term used in English law. By a statute of Richard II, it is forbidden for anyone claiming land to make a forcible entry on it. However good his title, he must not assert it by force, or he will be guilty of a breach of the peace, and be liable to a fine.

**Forcible Feeding.** Administration by force of food to a person who refuses to take it. Liquid nourishment is introduced into the stomach through a tube passed down the throat, or sometimes through the nostril. The procedure is often necessary with mental patients, or prisoners who refuse to eat. See Hunger Strike.

**Forcing.** Art of bringing flowers, fruit, and vegetables to a state of maturity at an earlier date than

in ordinary circumstances. Any heated greenhouse can be used as a forcing house, but where this is not available fresh stable manure may be spread at the bottom of a pit, about 3 ft. in depth, and, when the rank steam has escaped, covered with a thick layer of good, rich loam, a cold frame or a series of portable hand-lights being placed over it. The decaying manure will create a high temperature, and the frames can be used for starting all half-hardy plants, and when the temperature of the decaying manure falls, the frames will serve to grow rhubarb, sea kale, and sometimes mushrooms. If the temperature falls too rapidly, it must be restored by the addition of fresh manure and litter. See Gardening.

**Ford** (Anglo-Saxon). Point in a river or lake at which man or beast can cross on foot. Fords and bridging facilities have fixed the site of all important riverine towns. Modern London includes the old city, built at the then best bridging point nearest the sea, and Westminster, founded where the Thames could be forded before London Bridge was built.

**Ford, EDWARD ONSLOW** (1852-1901). British sculptor. Born at Islington, July 27, 1852, he studied at Antwerp and Munich. In 1875 he first exhibited at the R.A., becoming A.R.A. in 1888, and R.A. in 1895. Among his works are the Gordon group, 1890, of which replicas are at Chatham and Khartum; the Queen Victoria Memorial, Manchester, 1901; Folly (Tate Gallery). His many portrait busts are marked by delicate modelling. He died Dec. 23, 1901.

**Ford, FORD MADOX** (1873-1939). British author. Son of the music critic Francis Hueffer, and grandson of Ford Madox Brown (*q.v.*), he changed his surname in 1923. He published at 20 his first book of poems, *The Question of the Well*, under the pseudonym Feuil Haig. A prolific writer and brilliant critic, he was a distinguished personality in the society of his day. Among his best-remembered works are two novels written in collaboration with Joseph Conrad: *The Inheritors*, 1901, and *Romance*, 1903. Outstanding, too, was his sequence of four novels in which the characters were set against the background of the First Great War: *Some Do Not*, *No More Parades*, *A Man Could Stand Up*, and *The Last Post*, 1924-28. The founder and first editor of *The English Review* he later wrote *No Enemy*, 1929: *When the Wicked Man*,

1932; *The Rash Act*, 1933. Besides a distinguished biography of Conrad, he wrote monographs on Rossetti and Henry James. He published his reminiscences, *Return to Yesterday* in 1931, and a sequel, *It Was the Nightingale*, in 1934. Other works include critical studies of Henry James and of the Pre-Raphaelites. He knew France intimately, published a book on Provence in 1938, lived in Paris for many years, and died at Deauville, June 26, 1939.

**Ford, HENRY** (1863-1947). An American industrialist. He was born on a farm near Dearborn, Michigan, July 30, 1863, the son of an emigrant farmer from Cork. He found work in an engineering shop in Detroit, and was also for a time a jeweller's assistant. Later he joined the Detroit Edison Co.

as an engineer, and experimented with a petrol-driven motor vehicle, completed 1892. After success with racing cars, Ford was able in 1903 to found at Dearborn his own company, destined to become the largest motor manufacturing concern in the world.

In 1914 he instituted a scheme of profit-sharing for his employees, and afterwards founded a trade school as part of his self-supporting organization. Something of Ford's independence of character at this time is shown in his much-quoted phrase, "History is bunk." Hoping to use his influence to end the first Great War by negotiation, he

chartered a "peace ship" in 1915, and paid a vain visit to Scandinavia. When the U.S.A. went to war in 1917, Ford made munitions.

His policy of paying operatives at higher rates than were normal led to disagreement with the code put forward in 1933 by the U.S. National Recovery Administration. Although forced to make concessions to the code, he remained an opponent of the New Deal. He was president of the Ford Motor Co. until 1918, and again during 1943-45. He died April 8, 1947.

Ford's only son, Edsel Bryant (1893-1943), was president of the company from 1918 until his death; and a grandson, Henry (b. 1918), succeeded in 1945.

The car that made the Ford name and fortune was the Model T ("tin Lizzie"), of which 15,000,000 were produced between 1908 and 1928. It embodied the principles of simplicity in manufacture and operation, lightness of construction, and cheapness in initial and running costs. Farm tractors, known as Fordsons, found a similar world market. After the First Great War, Ford established works in several countries, including that at Dagenham, Essex, claimed to be the largest in the world. Small 8 and 10-h.p. four-cylinder cars appeared, and in 1931 the V8 (eight-cylinder), a larger vehicle with an exceptional performance for its price. The company produced transport aircraft of its own design, and in the Second Great War operated the gigantic Willow Run plant, where 8,800 Liberator bombers were made. Aero-engines, including over 34,000 of the Rolls-Royce Merlin type, were also turned out by mass production. Consult *My Life and Work*, 1922; *Today and Tomorrow*, 1926, both H. Ford and S. Crowther; Henry Ford, J. G. de R. Hamilton, 1933.

**Ford, JOHN** (1586-c. 1639). English dramatist. Born at Islington, Devon, April 17, 1586, he spent a year at Exeter College, Oxford, and then entered the Middle Temple. His reputation rests on his tragedies 'Tis Pity She's a Whore, 1626; *The Broken Heart*, 1629; and the historical drama of Perkin Warbeck, 1634. He collaborated with Dekker, Rowley, and Webster, with the two first in *The Witch of Edmonton*, c. 1621; with the last in *A Late Murder of the Son upon the Mother*. H. de Vocht's edition of his works appeared in 1932.

**Fordwich**. Parish and village of Kent, England. It is 2 m. N.E. of Canterbury, and was once a

Henry Ford, American industrialist

Ford. The American car-builder, Henry Ford, seated in his first model, completed in 1892

place of importance. In the Middle Ages and later, the Stour, which flows by here, was navigable, and Fordwich was a port serving Canterbury and a corporate member of the Cinque port of Sandwich. It has an old church, S. Mary's, with a Norman shrine. The old sessions house still stands, and there are remains of the port. It was a borough until 1884, when it lost its mayor and corporation under the Act of 1883.

**Forecastle** or **Fo'c'sle**. Forward portion of a ship, usually providing living accommodation for the crew. In new steamers, however, particularly liners, the crew are housed in cabins farther amidships. The term fore-castle is derived from the raised platform, fitted to the bows of medieval warships, from which the archers fired into enemy vessels. A monkey fore-castle is a small deck below the level of the fore-castle proper.

**Foreclosure** (old Fr. *forclos*, shut out). Term used in English law. When a mortgagor has failed to pay the debt in accordance with his covenant, the mortgagee may take possession of the land or other security; but the mortgagor has, at any time, the right to come and say, "Here is your money and interest, give me back my security." This right is called an equity of redemption. If the mortgagee desires to exclude the mortgagor from this equity, he must bring an action to foreclose, when the court orders that if the mortgagor does not redeem within a certain time, generally six months, the equity shall expire, and the mortgagee shall become the owner of the security. See Mortgage.

**Foreign Jurisdiction Acts.** Acts of 1890 and 1913 which give the British crown jurisdiction over British subjects in certain foreign countries to the exclusion of the courts of those countries. Jurisdiction usually arises from some treaty, but if a country is not subject to any regular government the Act confers jurisdiction. Of recent years, as the legal systems of even backward foreign countries have developed, this jurisdiction has decreased. See International Law.

**Foreign Law.** English law treats foreign law solely as a matter of fact. If an English court has before it a case that turns on a question of foreign law, it will not refuse to decide the dispute. For its satisfaction, therefore, qualified lawyers of the country in question must prove in evidence

Foreign Office, London, seen from St. James's Park

what the law is, and on that the case will be decided.

**Foreign Legion** (Fr. *Légion Étrangère*). French corps raised in 1831, to utilise the services of foreigners sympathetic to the French conquests in Algeria. It was formed at first in battalions like infantry of the line, but with varying numbers according to its strength. In 1884 the legion was divided into four battalions, to which a fifth was added in 1891. No Frenchman can serve in its ranks unless he renounces his nationality. The officer commanding is authorised to accept recruits of any nationality without inquiring as to their antecedents, and this has enabled many desperate characters and fugitives from justice to find refuge in the corps. Recruits must be between 18 and 40 and sign for a period of four years with the option of re-engaging.

In peace time the Foreign Legion used to garrison the French colonies in Indo-China and North Africa. It greatly distinguished itself in France in both Great Wars, serving with the Free French forces in 1944-45. Shortly before the Second Great War it was reorganized into two regiments of four infantry battalions, one cavalry regiment, a regiment of artillery, and a battalion of engineers. Attached to each regiment were disciplinary companies known as Zephyrs, in which offenders were drafted for service in the unhealthiest colonies.

The Spanish government maintains a Foreign Legion for service in Morocco.

**Foreign Office.** A British government department. Its head, the secretary of state for foreign affairs, has charge of all business affecting the relations of Great Britain with foreign powers. He formulates policy, appoints, sends out, and supervises ambassadors, consuls, and other diplomatic agents, and by various means, not excluding the

use of secret agents, keeps himself acquainted with the course of affairs abroad. The Foreign office is staffed by members of the foreign service which was created in 1943 by the unification of the former Foreign office and diplomatic, consular, and commercial diplomatic services, and was extended in 1946 to include overseas staff of the former ministry of Information.

Until Sir Edward Grey became foreign secretary in 1905 the position was almost invariably filled by a peer, among the holders being Lords Palmerston, Clarendon, Salisbury, Rosebery, and Lansdowne. Before 1782, when the foreign secretary first came into existence, the control of foreign affairs was divided between the two principal secretaries of state. The secretary is assisted by a parliamentary and a permanent under-secretary, and his office, entered from Downing Street, overlooks St. James's Park. A minister of state to assist the foreign secretary was appointed 1943; a similar appointment was made in 1945.

**Foreign Service.** A British government service concerned with international affairs, political, social, and economic. In 1943, the Foreign office and the former diplomatic, commercial diplomatic, and consular services were amalgamated into a distinct service of the crown entirely separate from the home civil service. Recruitment is by competitive entrance examination; a period abroad at the expense of the state follows. The examination is conducted by the Civil Service Commissioners. A proportion of the annual vacancies may be allotted to entrants nominated by a selection board. In 1946 women were admitted on equal terms with men, but their number was limited to 10 p.c. of the total entrants.

**Forel, AUGUSTE** (1848-1931). Swiss psychiatrist and myrmecologist. Born Sept. 1, 1848,

Auguste Forel, Swiss psychiatrist

he was trained as a physician, studied psychotherapy, and in 1879 became director of a mental hospital near Zürich, where he remained nearly 20 years establishing

an international reputation as a neurologist, and one of the most eminent alienists of his day. He was also an early supporter of eugenics. His best-known work was *La Question Sexuelle*, 1905, translated into many languages, including English, evolving a new theory of the connexion between nerve fibres and brain cells. After leaving Zurich he devoted himself to a personal crusade, travelling all over Europe to make war against drink and sexual immorality and in support of internationalism and education. At the age of 68, partially crippled by paralysis, he became an active socialist.

From his schooldays his lifelong hobby was the study of ants, and his eminence as a myrmecologist was even more widely based than his repute as a psychiatrist. His collection of ants comprised over 6,000 species, races, and varieties. Forel died July 27, 1931; his autobiography was published posthumously (Eng. trans. B. Miall, 1937).

His brother François Alphonse (1841-1912) became famous for his geographical and geological studies and as a seismologist. Professor at Lausanne, 1869-95, he wrote *Le Lac Léman*, 1886. He died Aug. 8, 1912.

**Foreland, NORTH AND SOUTH.** Two chalk headlands on the coast of Kent, England. The North Foreland, about 2½ m. S.E. of Margate, is the Cantium of Ptolemy, and has a lighthouse 188 ft. above sea level, with a light visible at 20 m. The South Foreland, 3 m. N.E. of Dover, has two light-

houses respectively 375 ft. and 275 ft. above sea level, and visible at 26 m. and 23 m.

**Foreshore.** Part of a beach or seashore which lies between the extreme limits of high and low water marks, i.e. is covered at high tide and uncovered at low tide. The extent of the foreshore depends partly upon the slope of the ground and partly upon the height

of the tides. The boundary has been fixed, by English law, as the mean between the high and the low water mark. Foreshore is vested in the crown. See Coast.

**Forest.** Term originally applied to a royal demesne set apart for the preservation of beasts of the chase and to afford the sovereign facilities for hunting. Not necessarily wooded or uncultivated, it was frequently called forest only because forest law was applied to it. It consisted of vert and venison. The former comprised the high wood, underwood, and turf; the latter the beasts of the forest, chase, and warren. In Scotland the term deer-forest is still used to describe an extensive region quite devoid of timber. In general, however, the word forest (late Lat. *for-esta*, ultimately derived from Lat. *foris*, out-of-doors) now means a large tract of uncultivated land thickly wooded.

Forests are of two kinds—temperate and tropical; and the temperate are subdivided into deciduous forests of oak, elm, maple, beech, birch, and other temperate hardwood trees whose leaves fall every autumn, and coniferous forests of fir, pine, larch, and other evergreens which

19th century has also been cleared though vast stretches remain. Some 450 million acres of the U.S.A.—close on a quarter of its whole area—are still forested. Oregon is now the most productive state. Fire is a serious menace—millions of acres are burnt annually. Canada has more than 750 million acres, of which about 490 million acres are accessible and productive; British Columbia produces more than half Canada's total of pulpwood. Production, that is to say, in N. America, has shifted to the Pacific side of the continent, the best of the areas in the E. having been stripped.

The chief timber exporting country of Europe is Sweden, with 57 million acres of forest. Germany has over 30 million acres; much of it has long been under state control and worked on a scientific system. The making of clocks, brooms, musical instruments as well as the production of timber was encouraged by successive governments. Finland, with 62 million acres of forest, produces timber, wood-pulp, and paper. More than 40 p.c. of the U.S.S.R. is forested; she and Canada possess the world's chief reserves of softwood. All the Russian forests are under government control, but the peasants have the use free of some 73 million acres. The exploitation of the Russian forests, however, presents great difficulty, since timber can be handled satisfactorily only where it can be floated down a river to a port or a manufacturing town, and rivers of Siberia and N. European Russia, where the greater part of the Russian forests lies, flow into the frozen Arctic Sea, and are themselves frozen for a large part of the year.

Oak, the principal temperate hardwood, does not grow S. of the equator; it grows chiefly in the forests of Central Europe, Canada, the U.S.A., and Japan. Great Britain's unique "brown oak" is much in demand for furniture and panelling.

From the forests of the tropics come the most beautiful and valuable cabinet woods. Mexico, Honduras, and other parts of tropical America are the home of mahogany, W. Africa of the so-called African mahogany, India of ebony, Central America and the W. Indies of rosewood and cedarwood. Burma, Siam, India, and Java produce teak, W. Australia the redwood of the eucalyptus tree. But the forests of the tropics

Foreland. The North Foreland lighthouse S.E. of Margate and, on left, the chief South Foreland lighthouse, both well-known landmarks on the coast of Kent

produce softwood and pulpwood. Down to historical times, much of central and northern Europe was covered with forest, and even in Great Britain there are today stretches of woodland (e.g. the New Forest) which are remnants of the forests that once clothed the island. Over those parts of Europe most suitable for agriculture and industry, the forests have been gradually cleared. Only Scandinavia, N. Russia, and Finland have extensive forests today.

Much of the forest that existed in N. America until the mid-

are far more mixed than those of the temperate zones, and are choked with a dense undergrowth and a wealth of climbing plants, so that it is difficult to extract the particular tree required.

The increased demand for timber and wood pulp leads to the decrease of temperate forests much faster than nature unaided can replace them, and governments in both N. America and Europe take steps to conserve their remaining forest, and to replant as trees are cut down. The clearance of large tracts of land formerly under forest has had an adverse effect in parts of N. America, reducing rainfall (large masses of trees cool winds passing over them, with consequent precipitation) and leading to soil erosion by the resulting dry winds. See Forestry.

**Forest Bed.** Series of deposits formed above the Pliocene Weybourne Crag and occurring beneath the glacial boulder-clay cliffs on the Norfolk coast. It comprises a lower fresh-water bed of clayey silt, an estuarine forest-bed (20 ft.) above, with stumps of trees and bones of mammals, and an upper bed of sand and blue clay (2-7 ft.), containing fresh-water shells. See Pliocene.

**Forest Cantons.** Four cantons of Switzerland, enclosing the Lake of Lucerne (Ger. Vierwaldstätter See). They are Unterwalden, Uri, Schwyz, and Lucerne.

**Forester, CECIL SCOTT** (b. 1899). British author. Born Aug. 27, 1899, he went to Dulwich College. He began as a writer of biographies. A psychological thriller, *Payment Deferred*, was made into a play, and an early naval story, *Brown on Resolution*, into a film. Other successful novels were *The General*, and *The Gun*. In *The Happy Return*, 1937, appeared Horatio Hornblower, a sea captain in the Napoleonic Wars, who was to go through several books and become a commodore and a peer; one Hornblower story, *A Ship of the Line*, won the James Tait Black prize in 1938. *The Ship*, 1943, was a study of the personnel of a cruiser in the Second Great War, based on Forester's journeys in H.M.S. *Penelope*. Settling in the U.S.A., Forester was left paralysed by a serious illness, but continued to write, publishing an outstanding novel, *The Sky and the Forest*, 1948.

**Foresters, ANCIENT ORDER OF.** British friendly society. Founded in 1834 to provide its members and their dependants with weekly allowances during sickness, old age,

Foresters' arms

or widowhood, it is one of the largest societies in the country. It retains much of the traditional ritual associated with membership, but this is not compulsory upon members. It is organized in autonomous courts and districts which owe a certain allegiance to the central body, and the government is vested in the high court of the order which meets annually in different cities. Contributions vary according to the benefits desired. The order has spread to America and the British dominions. See Friendly Societies.

**Forest Gate.** District of Essex, England, and an E. suburb of London. It is 5½ m. by railway N.E. of Liverpool Street station. There are chemical and other industries. Mostly included in W. Ham and E. Ham. Pop. 18,697.

**Forest Hill.** Residential dist. in the London metropolitan borough of Lewisham. It is 5½ m. by electric railway S.E. of London Bridge station. The Horniman Museum, standing in a public park, and built at a cost of £40,000, was opened to the public in 1901. The district was heavily damaged by German bombs in 1940 and flying bombs in 1944. Pop. 16,777.

**Forest Marble.** Name of a geological formation comprising

shelly and flaggy limestones. Alternating with layers of clay or marl, it is one of the Great Oolite group of Jurassic stratified rocks, and occurs in Dorset, Somerset (135 ft. in thickness), Wiltshire, through Oxfordshire into Buckinghamshire, where limestone thins out and is thence represented by clays. The formation is named after Wychwood Forest, Oxfordshire, where it was formerly quarried for building stone.

**Forest Reserves.** Name given in the U.S.A. to areas set aside for the conservation of trees and now known as national forests. Under legislation begun in 1891 and steadily expanded some 178 million acres in 158 forests, including Alaska and Puerto Rico, are administered by the U.S. forest service. Individual states administer 20 million additional acres and local communities a further 2,500,000 acres.

Canada also has forest reserves, about 143,000 sq. m. having been set apart—32,000 in Quebec, 30,000 in British Columbia, 19,000 in Ontario, 14,000 in Alberta.

**Forest Row.** Parish and village of Sussex, England. It is 3 m. S.E. of East Grinstead, with a rly. station, and is a convenient starting-point for a visit to Ashdown Forest. Between Forest Row and East Grinstead are the ruins of Bramletye House, home of the Lewknor family, and theme of a romance by H. Smith. Pop. 3,815.

## FORESTRY AND AFFORESTATION

H. G. Champion, F.R.S., Prof. of Forestry, Oxford Univ.

*An explanation of what forestry is, and how and why it is carried out, in temperate woods and forests, with particular reference to the growth of trees for timber. See also Forest; Timber; and entries dealing with particular trees, e.g. Beech; Larch; Oak*

Forestry is the general management of woods and forests, including the creation of woods on bare or scrub covered land. It is an applied science like agriculture, dealing with trees as a crop rather than individually; and also, in the main, with natural tree growth rather than with plantations. It has to do essentially with the growing of trees, though it may extend to the felling and extraction of timber and other natural tree products from the forest, together with the necessary processing.

The value of timber greatly exceeds that of all the other forest products, such as resin, cork, tanbark and charcoal.

The forester must have a fair acquaintance with all branches of forestry. First comes the care of existing woods and the raising of

young crops and plantations, termed silviculture. This involves knowledge of everything affecting the growth of trees as crops and is primarily a biological science based on botany, understanding of soils, and climatology; it includes appreciation of the object, methods, and results of human interference with the natural processes of forest life.

In Great Britain, where self-sown seed from older trees rarely gives sufficient and sufficiently rapid young growth to replace the parent crop, it is usual to plant out small trees raised in forest nurseries. In some types of forest, however, natural regeneration is left to itself, artificial regeneration (including sowing of seed) being used only to supplement the natural process, and in afforestation

1. An outward symptom of internal disease: red-rot fungus, *Fomes annosus*, on Scots pine. 2. Sulphur-tuft fungus, *Polyporus sulphureus*, on oak. 3. Larva of sawfly, *Lophyrus pini*, attacking young pine shoots. 4. Yew forest on Surrey chalk hills. 5. Wood of Scots pine grow-

ing in Surrey. 6. Horn-tail wasp, *Sirex gigas*, whose grub spends several years mining the solid wood. 7. Self-sown pine wood on a Surrey heath. 8. A Surrey beech wood. 9. Neglected oak trees, *Quercus robur*, with much wood but yielding little serviceable timber

**FORESTRY : BRITISH FOREST TREES AND SOME PESTS WHICH THREATEN THEIR GROWTH**

(i.e. creation of new forests, or their re-creation where natural growth has been destroyed).

In the nursery, healthy, vigorous stock of a size found by experience to be most suitable for the planting operation contemplated is raised as quickly and cheaply as possible. Sometimes the seedlings are put out directly into the forest from the seed bed, usually after two seasons' growth; more often they are first lined out in another part of the nursery at some such spacing as 3 ins. by 9 ins. and left to grow another season or two before they are planted out; they develop a more suitable root system as a result of the move. Trees are planted out at various spacings related mainly to the anticipated rate of growth. A slow-growing hardwood like oak may be planted as close as 3 ft. by 2 ft., i.e. over 7,000 plants per acre, whilst a quick-growing softwood such as larch or Douglas fir may be planted at intervals of 5 ft. by 5 ft. (1,742 plants per acre), or even more.

#### Preparing Ground for Planting

Before planting, some preparatory work on the site is usually necessary, for example, clearing undergrowth or weeds, or working up the soil. If there is a thick layer of vegetable matter, ploughing or some other work will have to be done on the planting site so that the roots can penetrate readily into the underlying mineral soil. Draining may also be necessary. Planting can be done in various ways, the object being to get the roots firmly into the soil in as natural a position as possible without undue labour or expense. In some countries seed is sown in patches or lines. The kind of tree to be sown or planted on any given site, or the mixture to be used, has to be carefully selected, taking into account all the factors of soil and situation.

Young trees need protecting from competing weeds, and weeding and cleaning must be continued—for several years in the case of slow-growing trees such as oak—until the branches of the young trees overlap, and weeds no longer menace them. At this thickest stage it is almost impossible to force a way among them, but after some years the lower branches of the young trees die off for want of light, and it is then usual to "brash" or "brush up," by trimming off all the dead lower branches from the ground level up to six or seven feet. At this time, or a little later, trees whose stems

are ahead of the rest of the crop and badly shaped or coarsely branched (known as wolves) are removed, to allow of enhanced growth by adjoining better stems. Then over a long period the tree crop is periodically opened out by thinning, i.e. by removing the less satisfactory stems to give the remainder room for further development. If thinning is too heavy the branches will develop too strongly and the timber become knotty, whilst at the same time the total wood growth on the area is likely to be less than it could be; if it is too light the stems become drawn up and weak.

After a period varying with the kind of tree, rate of growth in height falls off and the aim of further thinning is to maintain good healthy crowns, and thus promote continued steady growth in stem-diameter. One problem of forestry is to find markets for the small timber removed in thinnings.

The age at which wood becomes mature and ready for felling and regeneration, called the rotation age, varies with the kind of tree, and the size of it most in demand. Where timber for sawing is grown the rotation is rarely less than about 60 years for the quick-growing softwoods like larch and spruce, and may be 150–200 years for oak; Scots pine and beech fall between these limits.

#### Coppicing the Wood

Tree crops of maturing or mature age are more open than young woods, and it is possible to have an underwood of smaller stems, especially with hardwoods. This may be planted or semi-natural, of hazel or various deciduous trees such as ash, sycamore, oak, or chestnut, and it is usually cut down (or coppiced) at intervals of 7 to 15 or more years, to yield poles and sticks. Sometimes the whole wood is coppiced, a new crop growing up from shoots from the stumps; this method was prevalent when wood for fuel was needed, and was particularly applied to oak when the bark for tanning was in good demand. Repeated coppicing leads to gradual deterioration of the crop as the stocks get old; where management is efficient, worn-out stocks are regularly replaced. Conifers cannot be managed by coppicing as they do not produce shoots when cut. They are, however, often underplanted (as is the shade bearing beech) below open crops of hardwoods or larch, to keep the ground covered and make fuller use of the land. When the over-

wood is due to be felled the under-planted crop should give a yield of small timber at the same time; hemlock and Western cedar (*Thuja*) are particularly suitable for use in this way.

A combination of coppice with larger trees (coppice with standards) is common. This may originate by the retention of a few picked stems evenly distributed over the area when a young crop is first coppiced. At each subsequent coppicing a few of these standards may be felled to provide larger timber, and a new lot of maiden standards be retained from seedling trees that have come up among the coppice, or by planting, or from the best coppice shoots still standing on a healthy vigorous stock. In time, the crop contains an open sprinkling of standards of several ages and sizes above the coppice growth. The standards are nearly always trees such as oak and ash which do not cast too dense a shade. This form of crop supplies continuously a wide range of material well suited to meet the varied requirements of an agricultural estate.

#### Adequate Space Important

When trees of all ages and sizes occur singly or in small groups throughout the wood, fellings should be made on a cycle, returning to each part of the wood every few years and taking out a selection of trees of all sizes, including some mature, full sized trees, but otherwise removing inferior trees and allowing adequate growing space for all that are kept. To retain the all-aged structure continuous regeneration must be ensured. Such selection forests are coming more and more into favour on the Continent; they call for highly skilled management.

Forests are subject to injury and disease of many kinds. There are risks from natural physical phenomena such as wind, frost, snow, and drought, varying with locality and from year to year. Exposure to strong winds, particularly if they are laden with salt spray, has a general stunting effect on tree growth, whilst storms may uproot or break trees on an extensive scale. A tree that has grown up exposed to wind is always more firmly rooted than one which has grown up sheltered by its neighbours. It is accordingly a guiding principle when arranging the sequence of fellings that trees should never be suddenly exposed to the wind by the felling of others to windward of them; this in turn means so arranging

that the older crops in which there will be heavy timber felling are towards the leeward side of the forest, with the fellings annually moving up the prevailing wind. Trees, *e.g.* spruce, which do not root so deeply, as *e.g.*, oak and pine, and so are more likely to be blown down, must not be planted on exposed sites or left standing alone in felling.

#### Damage by Frost and Snow

Snow also may uproot or break trees, and its weight often bends over young crops beyond recovery, particularly if they have been inadequately thinned. Frost damage is a serious risk in many places. Some species are particularly susceptible, *e.g.* ash, and should not be planted on sites known or likely to be frosty. Late frosts which kill the newly developed shoots and foliage can be very injurious, not only seriously checking growth but also causing forking of the stem or bad curvature where a side shoot takes the lead in place of a frosted leader. Considerable protection against frost damage is afforded to young growth by an overwood. Sometimes a hardy, quick-growing species is mixed with a slower, susceptible one as a nurse crop, to be removed when the danger is over.

Many forest trees are liable to insect damage, especially when growing in pure crops. Thus, it is commonly inadvisable to replant at once an area where a pine crop has been felled, owing to the great probability that the pine weevil, which breeds in the stumps, will attack the young plants and kill a large proportion of them; after about three years the food material in the stumps is exhausted and the weevils can no longer survive. Another very injurious insect burrows in the shoots of young pines and causes serious malformation. Defoliation by caterpillars is common, being particularly conspicuous on oak; it is difficult to prevent, and causes much loss of growth. Insect-eating birds should be encouraged as the most practicable method of minimising insect attacks.

The forester also has to contend against fungus diseases. Some, for example the honey fungus, kill young plantation trees outright; others cause cankerous growths deforming the tree and reducing its value for timber, the larch canker being a common example; yet others cause decay in the heartwood and render the timber worthless. Trees planted on unsuitable sites are prone to fungus

diseases, and some stocks are more susceptible than others. Rodents are the most serious enemy of British forests; in many parts of the country it is impossible to raise a plantation without protection from rabbits. Grey squirrels are destructive of beech, ash, and sycamore. Small rodents and birds, particularly the wood pigeon, are largely responsible for the failure of natural regeneration of oak and beech in England.

Protection against fire is very important, especially in conifer plantations. The forest is divided into blocks of moderate size separated by fire lines kept clear of inflammable material (often by ploughing), look-out towers are kept manned, and organization makes it possible to get men and extinguishing appliances quickly to an outbreak.

An important branch of forestry deals with the measurement of trees and crops, their rate of growth, and their valuation. The work of felling trees and extracting them from the forest with minimum damage and wastage is dealt with by the forest engineer, who often also carries out preliminary saw-milling on the spot.

#### Effect on Soil and Water Supply

Production of timber is often only one of the objects, and not necessarily the most important, of afforestation. Forests exert a considerable effect on the soil and water supply; they moderate temperature and give protection from wind. They also drain swampy land, rendering it more healthy, provide sporting and recreational facilities, and preserve wild life. Taking all the matters applicable to local conditions into consideration, the forester usually draws up a working plan, laying down all operations to be done each year for a period of years (usually 10) in each subdivision of the area, felling and planting, road work, drainage, maintenance operations, and improvements. Where scientific forestry is practised, the fellings and the composition and structure of the crop are usually regulated to give as nearly as possible the maximum yield in perpetuity, though in some cases, *e.g.* in state-owned forests, other considerations than maximum sustained production or maximum financial return may be given weight; thus, less paying kinds of trees may be grown for reasons of amenity.

Great Britain has an exceptionally low proportion of its land area

under forest, only  $5\frac{1}{2}$  p.c. or three million acres, and most of this forest produces far less timber than it might owing to low stocking and poor management. Less than 5 p.c. of British requirements of timber are home grown. There was no state organization or policy until the Forestry Commission (*v.i.*) was set up in 1919. Improvement of management in privately owned woodland is particularly needed in the hardwood forests of oak, ash, and beech, totalling about one million acres.

The climate of Britain is very well suited to the growth of coniferous timber, particularly in the W. parts, where good results have been obtained with some of the trees of the W. American forests, such as Sitka spruce and Douglas fir; whilst pine grows excellently on poor, sandy soil in the S. and E. which is of low agricultural value. On good sites the average rate of growth reaches about 170 cu. ft. per acre per annum for Douglas fir, 90 cu. ft. for Scots pine, 70 cu. ft. or less for oak.

**Forestry Commission.** Body formed in 1919 to promote the interests of forestry and develop afforestation in Great Britain. Developed from the Forestry sub-committee of the Reconstruction committee formed in 1918, it was set up as a result of the serious reduction in standing timber in Great Britain during the First Great War. It is a body corporate appointed every five years under the Forestry Acts of 1919-45, and consists of a chairman, nine commissioners (of whom all but one are unpaid), and four directors, one each for England, Scotland, and Wales, and one in charge of research. The aim of the commission is to replenish the supply of native timber by maintaining existing forests and by encouraging afforestation. The crown woods were transferred to it in 1924; by 1948 it owned 1,477,000 acres, of which 570,000 acres were planted. It also advises and makes grants or loans to local authorities and private landowners for the purpose of afforestation, and has power to take over the management of woodlands which it considers to be unsatisfactorily managed.

Expenses are met from a forestry fund, derived partly from a Treasury vote and partly from profits on the sale of timber and lands; expenditure for the financial year 1947-48 was £6,632,000. The Forestry Act of 1945 placed the commission under the control of the minister of

Agriculture and the secretary of state for Scotland (but not of their departments); transferred power to acquire land from the commission to the Agricultural commissioners; and allocated to the commission £20,000,000 to enable it to carry out afforestation involving the employment of 13,000 men and the planting (or replanting) of 365,000 acres, as the first part of a five-year plan.

**Forestry Corps.** Unit of the British army during the First Great War. To secure an adequate supply of timber for war purposes lumber units were formed in Canada, the first draft reaching England in April, 1916. The corps was formed from these battalions in Oct. and eventually numbered 18,000. In the Second Great War a forestry unit from Newfoundland was working in Great Britain in Nov., 1939. There was no distinct forestry corps but the work was performed by battalions or companies of specialists from Canada, Bermuda, Honduras, the Pioneer Corps, and Royal Engineers. There was also a forestry section of the Women's Land Army.

**Forez, MONTS DU.** Wooded range of mts. in the dept of Loire, France. They lie in the W. of the dept., and divide the basins of the Allier and the Loire. The loftiest summit is Pierre-sur-Haute, 5,380 ft. The range is also known as the Monts de la Madeleine and the Bois Noirs.

**Forfar.** Parl., royal, and mun. burgh, and the county town of Angus, Scotland. It stands in the

Forfar arms

valley of Strathmore, 12 m. N. of Dundee, and is a railway junction. The burgh's chief edifices are the county buildings, town hall, court house, and Meffan Institute. A public hall and a park were given by Peter Reid, a merchant here. The chief industries are the manufacture of linen and jute; others are bleaching and rope-making. The burgh is governed by a provost and council, and the corporation owns the gas and water supplies.

Forfar was a royal residence of Malcolm Canmore, whose castle on a hill of the N. of the town was taken and destroyed by Bruce in 1308; its site is marked by a cross erected in 1648. It was made a burgh in the 13th century. Forfar is one of the five Montrose

burghs which jointly return a member to parliament. Market days, Mon. and Fri. Pop. 11,032.

**Forfarshire.** This Scottish county has been officially known since 1928 as Angus (*q.v.*).

**Forfeiture** (late Lat. *foris factum*, something done outside). Deprivation of lands, goods, or other property, usually in consequence of a sentence passed by a court of law, or some breach of the law. In English law a person convicted of felony, treason, *felo de se*, and certain other offences, including striking a judge, forfeited all his lands and goods to the crown. This was abolished by the Forfeiture Act, 1870. At common law, also, an illegal conveyance of land, *e.g.* to an alien, before the Naturalisation Act, 1870, or to a corporation in mortmain, was similarly punished.

Leases frequently provide that the landlord may re-enter the premises and forfeit the lease if the tenant fails to carry out his obligations—*e.g.* to pay the rent or keep the premises in repair. The court will usually prevent the landlord from enforcing forfeiture if the tenant makes good his default. In the case of failure to pay rent the tenant may apply to the court for relief within six months of the landlord obtaining judgement. For breaches of other covenants, except where forfeiture is on the ground that the tenant has become bankrupt or his interest has been taken in execution, the landlord cannot

forfeit unless he has served a notice. By the Leasehold Property (Repairs) Act, 1938, which applies to the leases for 21 years or more of a house of rateable value of £100 or less, if the landlord more than 5 years from the end of the lease and with a view to the forfeiture of the lease serves a notice on the tenant to carry out repairs, the tenant may serve a counter notice, then no proceedings can be taken without leave of the court.

**Forge** (Lat. *fabrica*, workshop). In metallurgy, term with a wide meaning. It covers the simple hearth of the blacksmith, early furnaces such as the Catalan forge (*q.v.*), in which malleable iron was produced in Europe for a long period, and the modern extensive plant comprising furnaces, cranes,

hammers, rolling mills, presses, engines, or motors and boilers, which make up an iron-manufacturing works. It always relates, however, to the working of metals from a crude or semi-manufactured form, to a higher order, as distinguished from melting and casting. See Iron; Steel.

**Forgery** (Lat. *fabricari*, to frame). English law term for making or altering a written instrument which purports to be valid with intent to defraud (or in some cases to deceive). The notion that forgery always consists in signing a false name, or imitating somebody's signature, is wrong. Thus, to alter the date or amount on a cheque, account, or receipt, though the signature is genuine, is forgery, if the alteration be made with intent to defraud. On the other hand, merely to subscribe a false name on a note or cheque may not be forgery at all if there is no fraudulent intent. The law on the subject is dealt with by the Forgery Act, 1913.

**Forget-Me-Not.** Hardy perennial plant of the family Boraginaceae, genus *Myosotis*. Natives of

Forget-Me-Not. Leaves and flowers of the perennial plant

Great Britain, their height is from 7 ins. to 18 ins.; the flowers are blue and yellow. Several cultivated varieties are raised from seed planted out of doors in spring, and transplanted to their permanent positions in the autumn when they will flower in the spring and summer of the following and successive years. The best position is a moist

corner of the rock garden. The well-known blue variety is *M. palustris* which, though found naturally by the sides of streams, will thrive equally well in the garden as an edging, or in small beds or borders in moist peaty soil. A rarer natural species is *M. palustris alba*, which has white flowers.

**Forging.** Production of articles of iron or steel or other metal by hammering, pressing, rolling, or otherwise shaping the metal while heated but not in a molten condition. It is distinguished from casting by the fact that the metal is never raised to a temperature sufficiently high to melt it.

It is almost certainly the most ancient branch of the whole art of metallurgy, and was first practised by primitive man in shaping

pieces of native copper into rough weapons or implements. It depends upon the property which metals possess, some more eminently than others, according to which they "flow" under pressure while in the solid state. In its broad sense it embraces all the operations of shingling, cogging, and rolling by which "merchant" bars and plates are produced; the works in which such operations are carried out, while frequently styled rolling mills today, were originally termed forges, and the term is still largely retained.

These processes involve, first, the proper heating of the crude mass of metal to the requisite temperature; and, secondly, the use of tools specially adapted to impart the desired shape to the heated mass of metal. They are modified more or less according to the metal which is to be operated upon—iron, steel, copper, magnesium, aluminium, gold, silver, or alloys of these. The forging proper will nearly always begin with a reducing operation, "drawing down" a piece of metal to a smaller size.

Thus, in the production of an ordinary stonecutter's chisel, a round or a six-sided bar of steel of the desired thickness will be taken. The end of this bar will be heated in the smith's fire, and as soon as the right temperature has been reached the bar will be withdrawn, the heated end laid on the smith's anvil and hammered out—drawn down—until it has assumed the required chisel shape. If the chisel is a small one the whole operation so far may be done by the smith himself with his hand hammer.

#### Principal Operations of Forging

Otherwise the chisel will be finished by the use of a "swage," which in this case will be a flat-faced tool held in a handle made of twisted iron rod. The smith will lay the face of this swage on the end of the chisel and his helper or striker will strike it with his sledge-hammer, thus producing a finished surface of the desired shape, free from hammer marks. The end of the bar will then be notched by means of a smith's chisel at a distance up the bar corresponding to the length of the chisel desired, and the piece broken off. It is not yet finished, however; it will be desired to flatten out and round off the blunt end of the chisel. That end is therefore heated again, the chisel is then withdrawn, and the end hammered or knocked upon the anvil, when it will be broadened out more or less, as required. This operation is called "upsetting." The production of this simple article

thus illustrates four principal operations of forging—heating, drawing down, cutting off, and upsetting.

Other principal operations are bending, holing, and welding. In the production of a great propeller or engine shaft which may weigh 100 tons, or of a 100-ton gun, the operations are essentially the same.

#### Drop or Die Forging

In the modern system of drop or die forging, the heated piece of metal is pressed into a die, a hardened steel form, by a hammer falling or dropping repeatedly upon the die. The hammer is worked mechanically, its weight amounting in large machines to 3,000 lb. Many of the parts of motor-cars, motor-cycles, bicycles, and other articles in iron, steel, and non-ferrous metals are made by drop forging. Bolts and nuts, screw blanks and rivets are now made chiefly by machine forging, in which the machine takes a heated bar of iron or steel, cuts off a definite length, shapes the latter to the form required, and ejects it automatically. See Casting; Metallurgy; Welding.

**Forging Press.** Instrument used in metallurgy. The increasing sizes and complexity of articles in malleable iron and steel required in

engineering particularly, such as heavy flanged plates, cranks, and crank shafts, began to make their production by means of the steam-hammer difficult. Attention was therefore directed to the hydraulic press as likely to prove a more effective appliance, and such objects are now largely produced by its aid. Very powerful presses, capable of exerting a total pressure of 10,000 tons, have been built for forging purposes. The illustration shows a press of this character with its pumps and control valves, adapted as it stands for the production of flanged wheels and other heavy flanged plates by direct pressure.

**Forisfamilialion** (Lat. *foris*, outside; *familia*, family). In Scots law, the alienation of a child from his father and exclusion from further inheritance, by marriage, by provision made for him by his parents in ante-nuptial settlement or other portioning, or by his own renunciation of his legal right to legitim (*q.v.*). The custom is derived from the Roman law of emancipation of a son from his father's power by fictitious sale and manumission, by imperial rescript, or by formal declaration, after which the son became independent (*sui juris*), quitted the family to which he formerly belonged, and, as a general rule, lost the rights of agnation.

**Fork** (Lat. *furca*). Instrument for holding or lifting. It consists of a handle, terminating in two or more prongs. An example is the table-fork of silver or other metal. A tuning fork (*q.v.*) is a two-pronged steel instrument which when struck gives a fixed and definite note, used to determine musical pitch. By analogy the word is used for something (*e.g.* a road) which divides into two.

The farm implement of this name has a wooden handle and two or more steel tines. The two-tined kind, when large, is known as a pitchfork, used for loading hay or grain. Short, stout, emptying forks, of similar pattern, serve for unloading, while turning and collecting forks are still smaller, but with the same number of tines. Digging forks possess three to five tines, which may be round, square, or flat. Additional leverage is given by a sharply bent neck, and a short handle is preferred. Dung forks, for dealing with farmyard manure and litter, usually have three or four curved tines of circular section. Caving, cocking, or pooking forks, for collecting and loading short material, are somewhat similar, but the tines are long and wide apart, while they are continued backwards above the neck

Forging Press. A, A'. Base and head connected by columns, a, a', a''. B. Stand attached to base and to upper part of which tables and dies are attached. C. Inverted platen attached to ram, D, which works up and down under hydraulic pressure. Platen slides up and down columns. E, E'. Retractor rams which pull up the platen after each downward stroke. F. Intensifier which puts final extra pressure on ram, D, and articles being made. G. Hydraulic pumps working rams. H. Flanged tire of small railway truck wheel receiving finishing press. Ram, D, may make from 30 to 80 strokes per minute, each pressing article a little nearer final shape. J, J', J''. Hydraulic connections conveying pressure to the various rams

and connected by a cross-bar, so as to prevent the forked-up stuff from falling off again.

**Forli.** Province of Emilia, N.E. Italy. Bounded E. by the Adriatic Sea and N. by the prov. of Ravenna, its area is 730 sq. m. The surface is flat and low-lying, and the soil fertile. The chief products are wine, grain, silk, and sulphur. Besides Forli, Rimini is in this prov. Pop. 421,770.

**Forli.** City of Italy, the ancient Forum Livii. The capital of the prov. of Forli, it stands in a fertile plain, intersected by the rivers Montone and Ronco, 40 m. S.E. of Bologna by the main rly. from Bologna to Brindisi. A walled town, it contains a cathedral (re-built), a citadel, 1361, utilised as a jail, a lyceum, technical institute, municipal art gallery, and town hall. The churches contain pictures and frescoes by local masters. A thriving trade is carried on in cattle, cereals, wine, silk, and hemp, while the manufactures include furniture, earthenware, machinery, headgear, shoes, and silk goods. Founded about 200 B.C., in the Middle Ages it was part of the exarchate of Ravenna. It experienced many vicissitudes during the quarrels of the Guelphs and the Ghibellines, and fell to the papacy in 1504. It suffered little damage in the Second Great War, British troops of the 8th army occupying it Nov. 9, 1944, after the Germans had withdrawn. Pop. 65,683.

**Forlorn Hope** (A.S. *fore-lioran*, to send forward, *hauife*, a troop). Military expression once signifying troops sent forward. The implication that they are to carry out a specially dangerous enterprise is a comparatively modern use of the expression. The French, Dutch, and German equivalents are *enfants perdus*, lost children, *verloren hoop*, lost troop, and *verloren Posten*, lost post. Cromwell issued the first campaign medal to the forlorn hope, or skirmishers, of the New Model Army; it was of pewter and was worn on the hat. In hunting phraseology, a hound that follows the chase in front of the rest of the pack is referred to as a forlorn or forloyne hound. In ordinary language forlorn hope is used of any hopeless undertaking, hope being erroneously identified with hope meaning expectation, a word of entirely different etymology.

**Form** (Lat. *forma*). Word literally meaning shape. It denotes the manner in which the matter or parts of a whole are combined. Thus, a table or a chair may be

made of pieces of wood, but the form of a table differs from that of a chair in the arrangement of the materials. Aristotle lays down four causes or principles of being—the material, the formal, the efficient, and the final. The three last-named on examination will be found to run into one another, leaving only the opposition of Form and Matter. Matter is possibility or potentiality (*dynamis*) which becomes actuality (*energeia*) by its conversion from indeterminateness into something definite. As an adaptation of the Platonic idea, form is the realization of the ideal, e.g. of the perfect table that a carpenter has in mind. See Matter.

**Form.** In music, the plan of construction, or the arrangement of phrases, sections, and movements. There is no limit to the possible varieties of musical form, but a few outstanding classes may be named. Binary form has two main divisions, as exemplified in the old air Barbara Allen; ternary form has three divisions, as in Charlie is My Darling. From these two germs most of the larger specific forms have been evolved, such as the rondo, the sonata, and all their derivatives. The fugue is essentially a contrapuntal movement of continuity, but it has an underlying basis of sectional form.

Many compositions bearing other generic names are also referable to these forms; e.g. many songs and short instrumental pieces are in simple ternary form, called also primary, song, or lied form; many marches are in rondo form; the minuet and trio, in a suite, or symphony, are each in either binary or ternary forms, while together, with the recapitulation of the minuet, they constitute a larger ternary form. See Minuet; Suite; Symphony; Trio.

**Formalin** OR FORMALDEHYDE (HCOH). Pungent gaseous compound first prepared in 1867 by Hofmann by passing methyl alcohol vapour and air over a heated platinum spiral. A 38–41 p.c. solution of formaldehyde is known as formalin, and is the form in which the gas is obtainable in commerce. A current of air drawn by an aspirator is passed over methyl alcohol and in contact with silver gauze, formaldehyde being formed. The gas is made to pass through a series of receivers containing water, until the water is saturated with the gas. Formalin is employed as a preservative and antiseptic. Combined with ammonia, formaldehyde yields hexa-methylene-tetramine, which, under the

name of hexamine, is used as an internal urinary antiseptic.

A recent discovery in chemistry is the production of formaldehyde by the action of light upon water, in imitation of the natural process by which it is created by a plant through the agency of chlorophyll. The latter, under the influence of sunlight, extracts carbonic acid gas from the air and combines it with water to form formaldehyde and sugar. In the laboratory, carbonic acid and water under the influence of ultra violet rays are made to produce a similar result. The process is known as photo-synthesis. By using a coloured water, pure formaldehyde was obtained without sugar by Professor Baly of Liverpool. Formaldehyde can be produced industrially by the direct catalytic union of carbon monoxide and hydrogen or by the oxidation of synthetic methanol.

Formalin is a powerful caustic; when mixed with ten times its volume of water it may be used for removing corns. A 30 p.c. solution may be used for treating ringworm of the scalp, and a solution of 1 in 500 as a mouth-wash. Formalin is not much used in surgery as an antiseptic, as it tends to retard healing. It is a powerful disinfectant and has the advantage that it does not injure coloured fabrics. Formaldehyde is widely used in plastics, condensing with phenol to give bakelite and with urea and related compounds to give amino-plastics.

**Formalism.** In philosophy, the tendency to consider mere form or externalities as the only valuable part of anything. Thus, the adherence to cut-and-dried rules, like those of formal logic, is formalism. The same applies to the rules of composition in sculpture or painting. The term is specially used of strict adherence to religious forms and dogmas characterised by the absence of a genuine religious feeling. Formalism is rather the reduction of such forms and dogmas to a written system.

**Forman, SIMON** (1552–1611). English astrologer and quack doctor. Born at Quidhampton, Hampshire, Dec. 30, 1552, he entered Magdalen College, Oxford, as a poor scholar, 1573. After experience as an usher in small country schools he claimed mira-

Simon Forman,  
English astrologer

culous powers, and in 1580 professed to be able to cure diseases. He studied medicine and astrology in Holland, and in 1583 started practice in London, wrote treatises on mathematics and medicine, and began to seek the philosopher's stone. Though frequently arrested, he worked among the poor in plague-stricken areas and obtained a large and far less honourable practice among court ladies; e.g. his aid was sought by Lady Essex to alienate the love of her husband and influence the affection in her favour of Somerset. Cambridge granted him a licence to practise medicine in 1603.

Richard Nicolas, in *Overbury's Vision*, 1616, thus refers to him:

Forman was that fiend in human shape  
That by his art did act the devil's ape

His philtres are alluded to in Jonson's *Epicoene*, and his career suggested much in Jonson's play, *The Alchemist*. He died Sept. 11, 1611, and was buried in St. Mary's church, Lambeth. His MSS. came into the possession of Elias Ashmole. A diary, 1564-1602, was published in 1849.

**Formation.** In geology, an old term used to denote a group of strata or rock-beds. They are distinguished by common lithological characters, such as the Upper Greensand formation (sandstone) and Gault (clay). Modern divisions of stratified rocks are based on fossils enclosed, which often prove strata of different lithological aspect to be of same age. For these divisions "stage" names are applied. e.g. Selbornian stage, which includes both Upper Greensand and Gault formations.

**Formby.** Urban district, market town, and watering-place of Lancashire, England. It is 7 m. S.W. of Southport, and has a railway station. Formby is really a residential suburb of Liverpool. Near are the Altcar Flats, on which the Waterloo Cup is decided. Pop. 7,957.

**Formby, GEORGE** (d. 1921). British comedian. Born James Booth, he was a native of Ashton-under-Lyne, and first appeared on the London music hall stage at the Royal Albert, Canning Town, in 1902. He achieved outstanding success in variety at the Tivoli by his simple Lancashire humour, his wheezy voice (long thought to be assumed, but actually due to painful pulmonary weakness which he turned to good account with high courage), and his burlesque of the familiar light comedian. He appeared in pantomime and revue, and among the songs he popular-

ized was the famous I was Standing at the Corner of the Street. He died at Warrington, Feb. 8, 1921.

His son George, who adopted the same surname, was born May 26, 1904. He became a jockey, but abandoned that career for the stage, playing first under the name George Hoy. From his first film in 1934 he was a popular comedian, and his later pictures included *It's in the Air*; *Trouble Brewing*; *Keep Your Seats, Please*. During the Second Great War he and his wife Beryl devoted themselves to entertaining British troops overseas, sometimes in theatres of war not visited by other artists.

**Forme.** In printing, a page or number of pages of type, or stereotypes, arranged or "imposed" for printing and secured or "locked up" in a metal frame called a chase. See *Printing*.

**Formentera.** One of the Balearic Islands, in the W. Mediterranean Sea, belonging to Spain. It is the smallest and most southerly of the group, and lies 7 m. S. of Iviza. Area 37 sq. m. The fertile soil yields abundant wheat. Fishing and salt-working are engaged in.

**Formia.** Town of Italy, in the prov. of Naples, until recently called Mola di Gaeta. Situated on the N. side of the Gulf of Gaeta, 48 m. by rly. W.N.W. of Caserta, it is a seaside resort. A Volscian town, known as Formiae, it stood on the Appian Way and was a residential district for wealthy Romans, remains of whose villas stud the coast. Here Cicero lived, and met his death, near his villa, Dec. 7, 43 B.C. The town has a little trade in olive oil and earthenware, and the surrounding districts yield an abundance of fruit. During the Second Great War, little damage was done, though the Germans looted the choir and sacristy of the church of S. Erasmo, and the best objects in the museum were removed to Naples, where they were destroyed. American troops of the 5th army captured Formia May 18, 1944.

**Formic Acid** (Lat. *formica*, ant). The lowest in the important series of fatty acids. Its chemical formula is  $\text{CH}_2\text{O}_2$ . It was first obtained by John Ray in 1670 by

Forme. Four pages of type locked up in a chase, making a forme ready for printing

distilling red ants with water, his observations being printed in the *Philosophical Transactions* of that year. Formic acid occurs in other animal and vegetable substances, but is now made by (1) heating to 60° C. in a retort a mixture of sugar, water, manganese peroxide, and sulphuric acid; (2) heating equal parts of anhydrous glycerine with oxalic acid and distilling the product. It has been used in the treatment of rheumatism, as it was observed that those liable to bee stings often found relief from rheumatic pain.

**Formication.** Sensation of insects crawling under the skin, a disorder of the sensory nerves resulting from prolonged intake of certain toxic substances, e.g. cocaine.

**Formicivora** (Lat. *formica*, ant; *vorare*, to devour). Genus of passeriform birds of the family Pittidae. They are long-legged birds and are widely distributed geographically.

**Formigny, BATTLE OF.** Fought between the English and the French, April 15, 1450. To strengthen the English cause in France a force under Sir Thomas Kyriel was sent to Cherbourg. About 2,500 strong, it was joined in Normandy by another 1,000 men, and this army, having taken Valognes, moved to Formigny, near Bayeux. There it was met by a French force and was routed.

**Formosa** or **TAIWAN.** Island province of China, off the S.E. coast. Formosa was Chinese territory from 1683 until 1895, when after the Sino-Japanese war it was ceded to Japan. The island proved

Formosa. Map of the island province of China

a valuable base for subsequent Japanese operations against China, and, in Dec., 1941, against the neighbouring Philippines. Its restitution to China was one of the decisions of the Anglo-Sino-American conference in Cairo, Nov., 1943. Military objectives were frequently bombed by Allied aircraft during 1944-45, and the formal surrender of Japanese forces in Formosa was signed at Nanking on Sept. 9, 1945.

An island of wonderful fertility and great natural beauty, it is divided sharply into two nearly equal portions. The W. side, facing China, consists of highly cultivated plains; the E., of lofty forest-clad mt. ranges, which extend to the E. coast, where the island faces the open Pacific with steep, perpendicular cliffs, rising in places to 6,000 ft. The capital is Taipei (*q.v.*). Other important towns are the ports of Kilung, Taitung, Anping, and Lukang; also Tainan and Chiayi. As the centre of the island is mountainous, the main rlys. run along the coast. There is a network of excellent highways. Chief products are 90 p.c. of the world's camphor, sugar, tobacco, salt, coal, and gold. The annual yield of sugar is 17,000,000 tons, the fourth largest of any country.

Between Formosa and Fukien on the mainland is a group of 21 small but strategically important islands known as the Pescadores (or Bokoto).

From 1895 to 1945 this group was also under the Japanese, who established a naval base at Mako and also air bases, but it is now part of the prov. of Formosa. Area (including the Pescadores), 13,889 sq. m.; pop. 6,500,000, of whom 94 p.c. are Chinese, the remainder aboriginal hill tribes.

**Formosa.** Territory of Argentina, in the N.E. of the republic. It lies between the rivers Pilcomayo and Bermejo, with Paraguay on the N. and E., the prov. of Chaco on the S. and the prov. of Salta on the W. It includes part of the Gran Chaco. The interior contains forests and swamps, abounding in game. Area, 29,143 sq. m. The capital is Formosa, a port on the river Paraguay, a centre for agricultural produce, cattle, tobacco, and sugar. Indians inhabit the interior.

**Formosa Strait.** Channel separating the island of Formosa from China. About 150 m. wide, it contains the Pescadores Islands, the largest of which is Hokoto.

**Formula.** In chemistry, a contraction showing what elements and how many atoms of each are contained in a molecule of a compound. Thus  $H_2O$ , the formula for water, shows that a molecule of water contains two atoms of hydrogen and one atom of oxygen. More complicated formulae show how the various atoms in a molecule are linked together and how they are arranged in space, thus:

phuric acid, shows not the actual arrangement in space, for this is usually not possible on a flat surface, but how the atoms are linked together. The formula for a molecule of common salt is  $NaCl$ , but crystals of common salt are not assemblies of molecules; they are groups of atoms or ions in which each sodium atom,  $Na$ , is surrounded and equally attracted by six chlorine atoms,  $Cl$ , and each chlorine atom is surrounded by

and equally attracted by six sodium atoms.

The molecule of benzene has the formula  $C_6H_6$  and is usually shown by this diagram,

This convenient formula is not strictly correct, as the molecule is a perfectly symmetrical hexagon and there is no physical evidence of alternate double and single bonds. The formula for acetic acid may be written as  $C_2H_4O_2$  or as  $CH_3COOH$  or as

but the molecule is not in reality a flat one. It is impossible to show by such formulae the structure of complicated compounds, and such structural formulae should be regarded as merely rough guides.

**Forres.** Royal burgh and market town of Morayshire, Scotland. It stands on the river Findhorn,

Forres arms

near the Moray Firth, 12 m. S.W. of Elgin. The principal buildings are the town hall, Falconer Museum, Anderson's Institution, and Municipal Buildings. An ancient monolith, named Sueno's stone, is said to have been placed here early in the 10th century. On Castle Hill was a royal residence in the 12th century. Woollen goods are manufactured. Forres is situated in a sheltered position at the foot of the Cluny Hills, and near is the Cluny Hill hydropathic. Pop. 4,169.

**Forster, ALBERT** (b. 1902). Danzig politician. He became the chief Nazi official of the Danzig district about 1930, as a member of the association of office workers in the German Labour Front. He then edited the Danziger Vorposten, urging a pro-Nazi policy. Raised to the Prussian state council, he was on Aug. 24, 1939, appointed by Hitler head of the Danzig state just before its incorporation by Germany. In the Second Great War he was known as gauleiter of Danzig and West Prussia, being responsible for the expulsion of Poles from territory

Formosa. Natives of Karenka on the beach. They are of Malay origin and are half savage

deemed to be German. Following the defeat of Germany he was captured at Hamburg by the 53rd Welsh div. late in May, 1945, and was handed over to the Polish government in Aug., 1946.

**Forster, EDWARD MORGAN** (b. 1879). British novelist. Born Jan. 1, 1879, and educated at

E. M. Forster,  
British novelist

1910, he dealt with the interaction of two types of character, those who live by convention and those who live by instinct. His masterpiece, *A Passage to India*, 1924, again emphasizing the importance of personal relations, was awarded the Femina Vie Heureuse and James Tait Black Memorial prizes. In 1927 he was Clark lecturer at Cambridge, when he dealt with Aspects of the Novel, and in 1937 he published a collection of essays, *Abinger Harvest*. His biography of G. Lowes Dickinson, 1934, was remarkable in that he made the undramatic life story of a man of letters and ideas intensely interesting. As a short story writer Forster occupied a high place, his best-known collections being *The Celestial Omnibus*, and *The Eternal Moment*. His quiet, clear speech and his wit made him an acceptable speaker and broadcaster. *Consult* The Writings of E. M. Forster, R. Macaulay, 1938; E. M. Forster, L. Trilling, 1944.

**Forster, JOHN** (1812-76). A British historian and biographer. Born at Newcastle, April 2, 1812,

John Forster,  
British historian  
After C. E. Perugini

and educated at Newcastle grammar school and University College, London, he became, in 1833, the literary and dramatic critic of the *Examiner*, and edited the *Daily News* in 1846. During 1847-55 he edited the *Examiner*, resigning on his appointment as secretary to the commissioners of lunacy. From 1861 to 1872 he was one of the commissioners. He died Feb. 1, 1876.

Forster is best known for his *Life and Times of Oliver Goldsmith*, 1848; and *Life of Dickens* (of whom he was the intimate friend and correspondent for over 30 years) 1872-74. He also wrote *Lives of the Statesmen of the Commonwealth*, 1836-39; *Arrest of the Five Members*, 1860; *Life of Sir John Eliot*, 1864; and vol. i of a *Life of Swift*, 1875. His collection of MSS., books, and pictures forms the Forster bequest at the S. Kensington Museum.

**Forster, WILLIAM EDWARD** (1818-86). British politician. Born at Bradpole, Dorset, July 11, 1818.

his parents were Quakers, and he was educated at a Quaker school at Tottenham. In Bradford he became a successful woollen manufacturer. He found time also for public work; writing and lecturing made him known, and in 1861 he was returned as Liberal M.P. for Bradford. He retained the seat throughout his life.

In 1865 Forster joined the Liberal ministry as under-secretary for the colonies, but he was soon in opposition. In 1868 he became vice-president of the council in Gladstone's first ministry. It fell to him to frame and introduce the important Education Act of 1870. He remained in office until 1874, and in 1880 returned to the difficult position of chief secretary for Ireland. In 1882 he resigned, as Gladstone released the political prisoners from Kilmainham, and it was not surprising when he declared against Home Rule. On April 6, 1886, he died at his London residence. *Consult* Life, Sir T. Wemyss Reid, 1888.

**Forsterite.** The magnesian end-member of the olivine series of minerals; magnesium silicate ( $Mg_2SiO_4$ ) in light-coloured orthorhombic crystals. It occurs in volcanic rocks or as a contact mineral in dolomite altered by igneous intrusion. *See* Olivine.

**Forsyte Saga, THE.** Sequence of novels by John Galsworthy. The original "saga" comprised three long stories: *The Man of Property* (1906), *In Chancery* (1920), and *To Let* (1921), with two linking short stories. These, reissued in one vol., 1922, as *The Forsyte Saga*, depict very fully the history of a large London family of the wealthy and apparently secure

W. E. Forster,  
British politician

middle-class between the years 1886 and 1920, which has considerable value as a social document apart from its merit as a study of human motives. The history was extended to later years in three further novels: *The White Monkey* (1924), *The Silver Spoon* (1926), and *Swan Song* (1928), which were reissued in 1929, again with two short stories, as *A Modern Comedy*. Even then, though the Forsyte story was completed, some of the characters were carried over into other books, viz. *Maid in Waiting*, 1931, *Flowering Wilderness*, 1932, *Over the River*, 1933. There were also several disconnected short stories about the Forsytes, many of them being collected into the volumes *On Forsyte 'Change* (1930) and *Forsytes, Pendycyes and Others* (1935). The success of the original Saga, a new experiment in publishing, led directly to a fashion for "omnibus" volumes of all kinds containing three or more separate books. *See* Galsworthy, John; Omnibus Books.

**Forsythia.** Genus of shrubs of the family Oleaceae. Natives of Japan and China, they have smooth, simple, or trefoil leaves, and scattered yellow flowers, abundantly produced in early spring, which makes the two species, *F. suspensa* and *F. viridissima*, favourites in European gardens. The genus is named after William Forsyth, an 18th century gardener.

**Fort** (Lat. *fortis*, strong). Fortified place of small size, surrounded by a ditch, moat, rampart, stockade, or other means of defence, and garrisoned with a small body of troops. Fort is a diminutive of fortress and sometimes refers to a small castle. The term was applied to trading posts set up by Europeans in N. America, Africa, and India; some rough shelter and protection was thrown up, and the fort served as a storehouse and rendezvous for the traders, and, in attacks, as a refuge. During the Franco-British wars in India in the 18th century the existing forts were strengthened and new ones erected. Forts are still used as defence points on the N.W. frontier of India. Some leading examples in both N. America and India developed into towns and retained the prefix, e.g. Fort Duquesne. In its modern sense, fort means part of a general system of fortifications. *See* Fortification; Fortress.

**Fort, PAUL** (b. 1872). French poet. Born at Reims, Feb. 1, 1872, he settled in Paris, where he

founded in 1890 the Théâtre des Arts for modern plays, e.g. by Verlaine and Maeterlinck. Fort also edited the Symbolist review, *Vers et Prose*. The first volume of his *Ballades Françaises* appeared in 1897, and was followed by over 30 more, under the same title, establishing Fort's reputation as one of the outstanding contemporary French poets. He is influenced to some extent by Laforgue, but intensely individual, using rhythmic prose as his medium. He also wrote plays, and a stimulating *Histoire de la Poésie Française* depuis 1850 was published in 1926. *Pron.* For.

**Fortaleza.** The capital of Ceara, Brazil, is usually known by the same name as the state. *See* Ceara.

**Fort Augustus.** Parish and village of Inverness-shire, Scotland. It is finely situated at the head of Loch Ness, on the Caledonian Canal, and is connected with Spean Bridge, 24 m. S., by a branch railway line. The fort, built originally in 1716 and enlarged in 1730, was taken by the Jacobites in 1745, and recaptured a year later by William Augustus, duke of Cumberland, in whose honour it was named. Purchased by Lord Lovat in 1857, it was presented by him in 1876, to the Benedictines, who transformed it into a monastery with college, hospital, and scriptorium, which in 1882 was raised to the rank of an abbey. Pop. 600.

**Fort Bayard.** Town and port of Kwangchowwan, S. China. Situated on the N. shore of Mandarin Bay, the town was formerly the administrative centre of that portion of French Indo-China leased from China. This territory was restored to China in Feb., 1943, and occupied by Japanese forces in the same month. There is an aerodrome near the town, which has steamer communication with Hong Kong, Macao, and Canton. Pop. 20,000.

**Fort Beaufort.** Town of Cape Province, S. Africa. It is on the Kat river, 63 m. by rly. W.N.W. of King William's Town, and is an important ostrich farming centre. It is also the headquarters of a district with pop. 17,374.

**Fort Belvedere.** Royal estate in Berkshire, England. Between Ascot and Sunningdale, 6 m. S. of Windsor, Fort Belvedere was completed in 1746 as a look-out post for troops returned from quelling the Jacobite rebellion and encamped in Windsor Great Park. In 1750 it became the official residence of the duke of Cumber-

land (q.v.) in his capacity as Ranger of Windsor Park. The duke mounted on its battlements the battery of 4-pdr. guns which had been used at Culloden; these guns are still at the fort and until Victorian times fired royal salutes. Fort Belvedere was converted into a country house by George IV. In 1932 it became the country seat of the prince of Wales, who as Edward VIII here signed his instrument of abdication on Dec. 11, 1936.

**Fort Capuzzo.** This Libyan fortress of the Second Great War is noticed under Capuzzo.

**Fort-de-France.** Town of Martinique, French W. Indies, formerly known as Fort Royal. On the W. coast, 15 m. S.E. of St. Pierre, it is the capital and chief commercial centre of the colony. Its commodious harbour is fortified, and it has an arsenal, law and commercial colleges, a library, and several hospitals. In the chief square there is a statue of the Empress Josephine. In Aug., 1891, the town was laid in ruins by a cyclone. Pop. 52,051.

**Fort Donelson, BATTLE OF.** Federal victory in the American Civil War, Feb., 1862. Fort Donelson and Fort Henry, situated 12 m. apart on the Kentucky-Tennessee border, were the two most important defences of the West, occupied by the Confederates in 1861. Grant immediately recognized the necessity of capturing them, and succeeded in seizing Fort Henry, although most of its defenders had escaped to Fort Donelson.

Moving against the latter with a combined naval and military force, Grant received a serious check, and on Feb. 15 the Confederates made an attempt to retreat to Nashville, but were stopped by Grant. The following day Buckner, in command of the fortress, asked for an armistice in which to settle terms of capitulation. Grant demanded unconditional and immediate surrender, to which Buckner agreed. This reply of the Federal general and the play upon the initials of his Christian names, U. S., gave him the sobriquet of Unconditional Surrender Grant.

**Fort Duquesne.** Eighteenth century stronghold in Pennsylvania, at the junction of the Monongahela and Allegheny rivers. During the French and English disputes about the sovereignty of the land W. of the Alleghenies, George Washington recommended the spot as a suitable site for a fort, and in 1754 the English began to construct one. The French

drove them away and themselves completed the work, calling it Fort Duquesne, after the French governor of that name. Attempts by Washington, and in 1755 by General Braddock, failed to recover it; but in 1758 General John Miles succeeded. He arrived there to find that it had been abandoned and destroyed. The English then began to build Fort Pitt, which grew into Pittsburgh (q.v.).

**Forté.** Italian term used in music, meaning strong or loud. It is sometimes represented by the abbreviations *for.*, or *f.* Its superlative, meaning very loud, is *fortissimo*, shortened to *ff* or *fff*, or very rarely *ffff*. *See* Musical Terms.

**Fort Erie.** Town of Ontario, Canada, on the opposite side of the Niagara river from Buffalo, U.S.A. It is 100 m. S. of Toronto by C.N.R., C.P.R., and other rlys. Abundant water power is used for industries, which include steelworks and aircraft factories. Pop. 6,595.

**Fortescue.** River of W. Australia. It rises in the Hammersley Range, flows in a N.W. course of 250 m., and discharges into the Indian Ocean in lat. 21° 10' S., a few miles below Cape Preston.

**Fortescue, Sir JOHN** (c. 1394-1476). English judge and writer. Though belonging to the Devon

Sir John Fortescue, English judge After W. Faithorne

family of that name, he was born at Norris, Somerset. He was educated at Exeter College, Oxford, and became a lawyer in London. In 1442 he was made chief justice of the king's bench, and he held the post until Henry VI lost his throne in 1461. He went abroad with Queen Margaret of Anjou in 1463, and was with her and her son Edward for some time, but in 1471 he was pardoned by Edward IV. Fortescue is best known by his writings. His treatise on the laws of England (*De Laudibus Legum Angliæ*) was published after his death, and several times since. He also wrote a book, the earliest of its kind, now known as *The Governance of England*. This was first published in 1714 as *The Difference Between an Absolute and a Limited Monarchy*, and under its other title, with an introduction by C. Plummer, in 1885.

**Fortescue, Sir JOHN WILLIAM** (1859-1933). British military historian. Born Dec. 28, 1859, a

younger son of the 3rd Earl Fortescue, he was educated at Harrow and Trinity College, Cambridge. He was private secretary to the governor of New Zealand, but devoted much time to military history. In 1899 appeared the first volume of his *History of the British Army*; in all 13 volumes were needed to complete this monumental work in 1930. This is the most complete history of its kind, and particularly valuable for the 18th century. Fortescue was librarian at Windsor Castle, 1905-26. He also wrote a *History of the 17th Lancers*, 1895, and an animal study, *The Story of a Red Deer*, 1897. Lecturer on military subjects at the universities of Oxford, Cambridge, and London, he received the K.C.V.O., 1926. He died Oct. 22, 1933.

**Fort Garry.** A former post of the Hudson Bay Co., erected 1835, on the site of which Winnipeg (*g.v.*) grew up. In 1873 the city was incorporated under the latter name. Old Fort Garry Gate, a castellated gate at the end of Broadway, is all that remains of the fort. A mounted unit of the Canadian army known as the Fort Garry Horse distinguished itself at Cambrai, Nov. 20, 1917.

**Fort George.** Fortress of Inverness-shire, Scotland. It stands on Moray Firth, 12 m. N.E. of Inverness, and was erected after the rebellion of 1745 to accommodate 2,000 men, and improved in 1784. There is ferry communication with Fortrose on the opposite shore of the Firth.

**Forth.** A river of Scotland which, flowing into the North Sea, forms as its estuary the Firth of Forth. The meeting of the hill streams Duchray Water and Avondu, near Aberfoyle, Perthshire, forms the Forth, which flows through Perthshire, Stirlingshire, and Clackmannanshire, mainly in an easterly direction. The total length as far as Alloa is about 53 m. Tidal to a point about 4 m. above Stirling, the river is navigable for 300-ton vessels as far as Alloa, for 100 tons to Stirling. Its chief tributaries are the rivers Teith and Devon and Allan Water. In the Carse of Stirling its course is extraordinarily sinuous, forming the so-called Links of Forth.

**Forth, FIRTH OF.** Name given to the estuary of the river Forth, on the E. coast of Scotland. The Firth begins at Alloa, and stretches to a line drawn S. from Fife Ness, being thus about 51 m. long and varying in width from one to 17 m. The chief islands are Inch-

Firth of Forth. Layered map showing the heights of the surrounding hills and depths of the estuary

keith, Inchcolm, Cramond, and the Bass Rock. Leith, Granton, Grangemouth, Alloa, Burntisland, and Methil are the chief harbours and fishing ports along both coasts. The Firth is spanned at Queensferry by the Forth (rly.) Bridge, and a swing road bridge at Kincardine-on-Forth, opened in 1936. A ferry service is maintained at Queensferry between Granton and Burntisland.

The Firth has great strategic importance. During the First Great War it was a base of the Grand Fleet; defences, forts, protective booms, etc., were constructed, and in the Firth off Inchkeith the German fleet surrendered, Nov., 1918. The first German air raid on Great Britain during the Second Great War occurred in daylight on Oct. 16, 1939, in this area, ships of the Royal Navy being attacked off Rosyth. R.A.F. aeroplanes engaged German aircraft over the mainland for the first time in this action. See Rosyth.

**Fort Hall.** Settlement in Kenya, E. Africa. It is situated between Nairobi and Mount Kenya, and is 4,500 ft. above sea level. A branch line from the Uganda rly. at Nairobi links it with Nanvuki.

**Forth Bridge.** Railway bridge in Scotland, begun in 1882 and opened for traffic in 1890. By its construction across the Firth of Forth, from S. Queensferry to N. Queensferry, a long detour of the rly. westward was obviated and direct connexion between Edinburgh and the N. side of the Firth established, while its clear height of 150 ft. and long spans gave headway for vessels of any size or type.

From the engineer's point of view, it marked an epoch in the history of bridge building. Its enormous clear spans of 1,710 ft. between supports were rendered possible by the use of steel and by the cantilever design of the superstructure. The bridge, which carries

two railway tracks, slightly exceeds 1½ m. in length. There are three main piers from which the six cantilever arms rise and project, the ends of which, in the main spans, support and are connected by long girder spans. The height of the cantilevers, over the piers, above water level is 361 ft. The extremities of the end cantilevers rest upon masonry piers whence the rly. is carried to the shore on approach viaducts comprising a number of comparatively small steel bridge spans and masonry arches. Each main river pier consists of four circular masonry supports resting upon caissons 70 ft. in diameter, and sunk to a depth of from 70 to 90 ft. below water level.

The structure, designed by John Fowler and Benjamin Baker, comprises 51,000 tons of steelwork and 142,000 cubic yds. of masonry, cost nearly £3,000,000, and took seven years to construct. On Oct. 16, 1939, German aircraft attempted to bomb it in their first raid on the U.K. in the Second Great War. See Bridge illus.

**Fortification.** Art or science of fortifying a town, city, river-crossing, coastline, or other strategic position in order to defend it against an enemy. In early warfare, defence was always stronger than attack, and fortifications allowed of prolonged resistance by an army inferior to its opponents in numbers, equipment, mobility, or morale. The earliest type of fortification was the thorn hedge. Alexander the Great found the villages of the Hyrcanians defended by thick hedges, and similar defences are used to this day by primitive tribes in Africa and Asia. Early Roman fortifications had become more elaborate, with parapets built up by alternate layers of earth, tree trunks, and large stones, the front being covered by a bank of earth

strengthened by a palisade of trunks or hurdle work.

With the development of the ram and catapult, the principal offensive weapons in classical warfare, something stronger than earthworks was required, and the fortress (*q.v.*) was evolved with stone walls which often attained a thickness of 40 ft. Later a number of such fortresses were built and linked by small forts. Under the Romans the art of fortification became highly skilled, and on the frontiers of the Empire fortified towns were built, wherever possible on high ground banking to a river in front and with steep slopes falling away to the rear and sides. A castle or citadel stood on the highest part, and the landward sides of the town were surrounded by an enceinte wall, broken at intervals by high towers; the outer sides being protected by a ditch. Any bridge over the river would be defended by a bridgehead on the far side, while towered stockades were built out from either bank above and below the bridge. Passage under the bridge was barred by chains or booms.

Gauls and Visigoths retained the old Roman fortifications, but rarely improved upon them; one notable exception was Carcassonne, which the Visigoths fortified on the Roman model in the 5th century and which, rebuilt in the 13th, remains a monument to the medieval engineer. Towards the close of the 15th century the increasing fire power of artillery rendered the Roman and feudal defences obsolete. High, massive walls offered too great a target for concentrated artillery fire; on the other hand, effective fire could be obtained by the besiegers only if they sited guns close to the walls.

#### Vanban's Developments

Accordingly bastions were built to project from the curtain wall. The bastion had two faces and two flanks, enabling a cross fire to be directed against the massed artillery of the besiegers, while fire from the flanks of the bastion raked any frontal infantry assault. Ravelins or outworks were added, which during the 16th-17th centuries were extended until they culminated in the step-by-step defence system initiated by the French engineer Vauban (1633-1707). Until Vauban's day, little effort was made to adapt the defences to the topographical features of the site. Vauban retained thick masses of masonry to withstand heavy artillery fire, but added

secondary lines of defence on which the garrison, if driven back, could still resist. Vauban thus anticipated the principle of defence in depth ultimately exemplified in the Hindenburg Line of 1917 and the Siegfried Line of 1939.

Vauban's theory of fortification continued throughout the campaigns of Marlborough and the Napoleonic Wars. Rapid development of artillery in the 19th century brought a great change. The rifled gun, with its greater range and penetrating power, made it necessary that the enceinte or circumvallation should be more amply defended. Therefore several small fortresses were placed in front of the main defences and sufficiently close to each other to give mutual support against attack.

The Franco-Prussian War, and particularly the siege of Paris, 1871, showed the uselessness of stone bastions and ramparts against modern artillery. Reinforced concrete and steel became the new material, with armoured cupolas and turrets for the artillery. That properly designed fortifications of this type could withstand high explosive was proved during the attack on Port Arthur by the Japanese in 1904. Port Arthur's fortifications included all the latest developments in armoured gun positions and

successive defence perimeters. Despite the use of 11-in. siege guns and the launching of repeated infantry assaults, they withstood a five months' siege, and fell only after the forts had been undermined by constant sapping.

#### In the First Great War

By 1914 the gun had regained the ascendancy, as was proved by the rapid fall of the Belgian fortifications under the fire of the German 17-in. siege gun. Liège, with its 12 armoured fortresses, fell in 11 days; Namur after four days' bombardment; the Antwerp forts in three. Manonville, on the French frontier, lasted only two days. Yet the obsolete fortifications at Verdun sustained tremendous punishment from artillery and were never reduced, though it was the trench lines of the advanced positions that actually stopped the Germans. Later in the First Great War both sides relied on field fortifications rather than fixed fortresses of steel and concrete. The former can be rapidly built in accordance with the latest tactical ideas; sited in positions most suitable at the time; better concealed from aerial observation; and provide greater opportunity for defence in depth. Exceptionally thick strong-points, or pill boxes, of reinforced concrete, are interspersed with minefields, wire entanglements, and

Fortification. Schematic diagram of a theoretical modern fortified position, giving all-round defence, without allowing for natural ground features

tank traps, while no section of the defences offers a large target to artillery or bombing aeroplanes. These principles were first applied on a large scale in the Hindenburg Line (*q.v.*).

Despite the lessons provided by the losses of their walled fortifications in 1914, both France and Belgium continued to rely upon that type for their defence; and the Germans adopted similar defences in their attempt to protect the Continent from invasion. The new Belgian system, the Albert Line, was breached by the Germans in the first rush of May, 1940, though the enemy's rapid successes were aided by the treachery of the defenders. France pinned her faith to the Maginot Line (*q.v.*), which embodied the latest theories of static defence in line. It is doubtful if the Maginot Line could have been carried by direct frontal assault; it fell because it was outflanked. But it lacked defence in depth, and had the Germans carried the main system the French resistance must have collapsed as there were no rear defence lines on which the French army could have fallen back.

Germany's Siegfried Line (*q.v.*) did afford defence in depth, having successive lines of gun positions, minefields, and tank traps. Had the Germans decided to hold it they might have delayed the Allied advance in 1945, but they were concentrating resistance on the Rhine. That the power of attack can overcome the strongest fortifications sited to the greatest disadvantage of the attackers was proved by the Allied assault on Germany's Atlantic wall in June, 1944. The attack was launched from the sea, one of the most difficult military operations, but air and artillery bombardment, particularly by the rocket gun, reduced all but the strongest positions to rubble, and broke the morale of the defenders sheltering in the depths of their emplacements.

The fortress system generally has become obsolete, and except in very favourable circumstances even defence in depth can do little more than delay an enemy well equipped with armour and heavy artillery. The invention of the flail tank, which clears the minefields, and the flame-throwing tank, which can burn out concrete and armoured positions, again gave the ascendancy to the attack. Russia halted the German advance in 1942 by means of the fortified zone—strongly defended islands of

resistance called hedgehogs (*q.v.*). But when the Germans tried to stem the Russian advance into the Reich by a similar system, armour and air power overwhelmed them.

**Fortingall.** Village of Perthshire, Scotland. It stands on the Lyon, 8 m. W. of Aberfeldy, and is a centre for tourists visiting Glen Lyon and Loch Tay. It has a fortification thought to be Roman, possibly prehistoric; a yew tree reputed 3,000 years old; and some regard this village as the birthplace of Pontius Pilate. Pop. 1,629.

**Fort Jameson.** Settlement in N.E. Rhodesia. On the Tanganyika plateau, it is about 300 m. N. of Tete by road and 125 m. W. of Lake Nyasa. It was until 1910 the headquarters of the administration of N.E. Rhodesia.

**Fort Johnston.** Settlement of Nyasaland, Central Africa, 6 m. S. of L. Nyasa. It is a trading port.

**Fort Knox.** U.S. gold depository. See Knox, Fort, p. 4878.

**Fort Lamy.** Capital of Chad territory, French Equatorial Africa. Situated on the Shari just below its confluence with the Logone and S. of Lake Chad, it is a centre of communication, for from it radiate roads to the lake, to Kano, Abeshir, Fort Archambault, Carnot, Yaoundé, El Obeid, and Khartum. It is the headquarters of the lieutenant-governor of the colony. During the Second Great War it was a vital link for the Allies in air communication between W. and E. Africa and Egypt; its airfield was a refuelling station. Fort Lamy was also the base from which Free French forces attacked Italian outposts in the Libyan desert and whence General Leclerc's column set out to join the British 8th army in Tripoli, Jan., 1943. The town was attacked by Axis aircraft but suffered little damage. Pop. 6,000.

**Fortnightly Review.** THE. London monthly review first published as a fortnightly, May, 1865, under the editorship of G. H. Lewes, and the chairmanship of Anthony Trollope. John Morley became editor in 1867, and made it a monthly. Its contributors have included J. S. Mill, T. H. Huxley, Herbert Spencer, Swinburne, Barrie, H. A. L. Fisher, Wells, Julian Huxley, J. Middleton Murry, W. R. Inge, Dorothy L. Sayers, and Harold Laski.

**Fort Peck Dam.** Dam on the Missouri river in N.E. Montana, U.S.A. Built by the U.S. engineer corps, it was begun in Oct., 1933, and completed in Oct., 1940.

This largest earth-fill in the world has a total crest length of 4 m. and a maximum height of 250 ft. It comprises a main section across the river valley of 10,578 ft. and a large dyke section on the W. bank 10,448 ft. long. The average width of the base is 3,500 ft., and the top, carrying a hard road, is 100 ft. wide. The dam contains 123,000,000 cu. yds. of earth, 7,000,000 cu. yds. of gravel, and 1,000,000 cu. yds. of rock. Four tunnels by-pass water releases from the reservoir. A power plant at the outlet of one tunnel is equipped with three turbo-generators having a combined capacity of 105,000 kilowatts. The water release from the other three tunnels maintains a navigational level on the Missouri.

**Fort Portal.** Chief centre of the Toro district, Uganda. It is a missionary station and native town about 25 m. N.W. of Mt. Ruwenzori. Pop. 25,000.

**Fortress** (O. Fr. *forteresse*, from Lat. *fortis*, strong). Permanent military strong-point, sited, garrisoned, and equipped to provide a point of resistance in case of attack, and to act as a rallying point for troops who may be compelled to fall back from more exposed positions. The earliest fortress was a palisade enclosure, such as is still employed by primitive peoples in tribal warfare. The Saxon fortress was an artificial mound enclosing a number of huts, in which the local population sought refuge in time of war. The Romans also used mound enclosures or fortified camps, but these developed into elaborate systems of fortification.

Most early fortresses were built of earth and wood, and it was not until the rise of the feudal system that stone fortresses were built on any great scale. The typical feudal fortress consisted of a large walled space, protected by a moat, and could be entered only through a strongly defended gate. Later the walls were machicolated, and corner towers were added to allow of flanking fire along the walls. With the development of artillery the individual fortress became generally obsolete. See Fortification.

**Fortress.** Official British name for the heavy bomber known to the U.S.A.A.F. as Flying Fortress (*q.v.*).

**Fortrose.** Royal, mun. and seaport town of Ross and Cromarty, Scotland. It stands on the Moray Firth, 9 m. N.E. of Inverness, on a branch railway line. There is a good harbour, and the fine

scenery, bathing facilities, and golf links attract many visitors. Fortrose was formerly the seat of the bishops of Ross, but the episcopal palace and cathedral were destroyed by Cromwell, who built his fort at Inverness with the stones. Pop. 875.

**Fort Royal.** Former name of the town of Martinique, French W. Indies, now known as Fort-de-France (*q.v.*).

**Fort St. David.** Ruined fort of Madras, India, in the S. Arcot district. It is on the Coromandel coast, less than 2 m. E. of Cuddalore New Town. At one time the site of Dutch and French settlements, the fort was bought by the English in 1690, together with the land within the radius of a "random shot of a great gun." The gun was actually fired, the shot indicating the extent of the boundaries. The name is supposed to have been given to the fort by a Welsh governor. The fort was captured by the French in 1758, who demolished the fortifications, but after changing hands again twice, it was finally restored to the English in 1785.

**Fort Sumter.** Fort in S. Carolina, U.S.A. It stands on a shoal at the entrance to Charleston

harbour, 3 m. S.E. of Charleston. It was bombarded by the Confederates, April 12, 1861, and surrendered the following day, the action immediately leading to the opening of the Civil War. In April, 1863, it was violently bombarded by the Federal fleet in the first of a series of naval and land assaults which ruined it by October.

**Fortunatus.** Character of a folk-tale found among many different races. It first appeared in print in a German form in 1509. Fortunatus is possessor of an inexhaustible purse, a wishing cap, and other marvels in different variants of the tale. The moral goes to show the little value to be put upon material treasures. The story was dramatised in Germany by Hans Sachs, 1553, and in England by T. Dekker, 1600. One named Fortunatus succoured the Apostle Paul.

**Fortunes of Nigel, THE.** Fifteenth of the Waverley novels, published in May, 1822. In it Sir Walter Scott followed his masterly portraits of Mary Stuart and Elizabeth Tudor with an equally brilliant character-study of James I, and supplied vivid pictures of early 17th century London, from Alsatia to the Court. Nigel Olifaunt, Lord Glenvarloch, the young Scottish

palmistry, astrology, crystal-gazing, lot-casting by cards or otherwise, and subjective processes.

The alien origin of fortunetelling in Britain is confirmed by the fact that it is not a common-law offence. Its punishment as a form of witchcraft by death, under a statute of 1563, was reduced by the Witchcraft Act, 1735, to imprisonment for one year and the pillory. Under the Vagrancy Act, 1824, any person who undertakes to tell fortunes, or uses any subtle craft, means, or device, by palmistry or otherwise, to deceive and impose upon any person, is liable to imprisonment as a rogue and vagabond. It was held in one case that intention to deceive was a necessary part of the crime, so that a person who honestly believed in his powers of prediction could not be convicted, but this was later overruled. Spiritualist mediums have also been convicted. See Divination; Palmistry.

**Fortune Theatre.** A London playhouse, in Russell Street, W.C.2. It was opened in 1924, and presented such notable plays as O'Casey's *The Plough* and the Stars, Lonsdale's *On Approval*, and Chekhov's *The Seagull* and *The Three Sisters* (Komisarjevsky's productions). After being (in conjunction with Drury Lane) the headquarters of Ensa (*q.v.*), it was reopened in 1946. The theatre has a seating capacity of 493.

**Fort Wayne.** City of Indiana, U.S.A., the co. seat of Allen co. At the confluence of the St. Joseph and St. Mary rivers, which here merge into the Maumee river, it is 105 m. N.E. of Indianapolis and is served by several rlys. and two airports. It contains Concordia College and several schools and institutions. An important rly. and trading centre, in a hardwood timber region, it has rly. workshops, flour mills, foundries, and chemical, piano, and soap factories, as well as making engines, machinery, oil tanks and pumps, and furniture. On the site of a fort built in 1794, Fort Wayne received a city charter in 1840. Pop. 118,410.

**Fort William.** A police burgh and tourist resort of Inverness-shire, Scotland. It stands on the E. shore of Lower Loch Eil, at the foot of Ben Nevis, 65 m. S.W. of Inverness, on a branch railway line. The town was known as Inverlochy when Montrose defeated the Covenanters, Feb. 2, 1645. The fort, erected by Monk in 1655 and rebuilt by Mackay in

Fort Sumter. The island fortress at the entrance to Charleston Harbour, the scene of fighting in the American Civil War

harbour, 3 m. S.E. of Charleston. It was bombarded by the Confederates, April 12, 1861, and surrendered the following day, the action immediately leading to the opening of the Civil War. In April, 1863, it was violently bombarded by the Federal fleet in the first of a series of naval and land assaults which ruined it by October.

**Fortuna.** In Roman mythology the goddess of chance or good luck. There were several temples in Rome erected in her honour, but the most famous seats of her worship were Antium and Praeneste. She is also called Fors Fortuna. In art she is represented with a rudder as symbol of her guidance of things, also with a cornucopia as a symbol of the prosperity she brought to mankind.

**Fortunate Isles.** Alternative name for the Islands of the Blessed, or the Elysian Fields, of early Greek

nobleman who comes south to petition the king; his devoted servant, Richie Moniplies; the profligate Lord Delgarno; the crabbed old courtier Sir Mungo Malagrowth; "Jingling Geordie" Heriot; the wealthy goldsmith; Margaret Ramsay, the modest but courageous heroine; and the unhappy ship-chandler, John Christie, are memorable characters in the work.

**Fortune-telling.** Revelation by non-rational processes of what is to befall a person in the future. As one of the principal aims of divination it is traceable from its first recorded manifestations in ancient Babylonia into early China and India. Thence it was brought across medieval Europe by the gipsies, who are recorded by Pepys as having practised the art at Lambeth under society patronage in 1688. As a modern superstitious survival it is associated with

The ruined Forum, looking north-west towards the Capitol the three pillars with architrave in the middle distance were part of the temple of Castor and Pollux

Top a reconstruction of part of the Great Forum in imperial times, with a religious procession passing the temple of Castor and Pollux. Beyond is the Basilica Julia

#### FORUM: CENTRE OF THE LIFE OF ANCIENT ROME

1690, successfully withstood siege by the Jacobites in 1715 and 1746; it was dismantled in 1860. Fort William is a starting-point for the ascent of Ben Nevis (*q.v.*). Industries are concerned with aluminium and distilling. Pop. 3,200.

**Fort William.** A port and city of Ontario, Canada, in Algoma dist. It stands at the head of Lake Superior, on the left side of the Kaministiquia river, its importance being due to its position at the head of navigation. It is 420 m. E.S.E. of Winnipeg, and is served by C.P.R. and C.N.R. It has a street rly. which goes to Port Arthur, 3 m. Steamers ply from here to the ports on the Great Lakes and the St. Lawrence, and there are immense elevators to handle grain brought from the W. In addition to its shipping, for which there is 28 m. of deep-water frontage, the city has flour mills, iron foundries, and other industries. It owns 31 m. of street rly., telephone, lighting, water, and sewerage systems. It was founded in 1801 as a Hudson Bay trading post. Pop. 20,585.

**Fort Worth.** A city of Texas, U.S.A., the co. seat of Tarrant co. On Trinity river, at the confluence of its Clear and West Forks, it is 30 m. W. of Dallas, has an airport, and is served by several rlys. The chief rly. centre of the S.W. and a port of entry, it is also the centre of the oilfield and cotton growing region of West Texas, the only primary grain market in the S., and a big livestock market and meat packing centre. It ranks third among U.S. cities in the volume of air mail handled. Products include flour, ranch and oil-field equipment, cotton goods and cottonseed, cement, footwear, and clothing. A bomber assembly plant, established 1941, produced in 1950 one B-36 bomber weekly. Three dams stand on the W. Fork. The city, incorporated 1873, occupies the site of a military camp established in 1849, which never became a fort. Pop. 177,662.

**Forty-Five, THE.** Name given by the Scots to the rising that took place in Scotland in 1745. Charles Edward (*q.v.*), the Young Pretender, landed and led an army into England, marching as far south as Derby, Dec. 6. The Scots then withdrew and were totally defeated at Culloden, April 16, 1746. This was the last serious attempt of the Stuarts to regain the throne. See Fifteen, THE.

**Forum.** Among the ancient Romans, any open space used for public business. More particularly

Fort William, Scotland. The town, with Ben Nevis in the background, viewed from Loch Eil  
*Hardie*

the term was applied to the open space in Rome, an irregular oblong in shape, lying between the Palatine and Capitoline hills, known as the Forum Romanum. Here the assembly of the people met; here magistrates and others addressed them from the tribunal or *rostra*. Adjoining were the Curia or senate house, the Basilica Julia and Basilica Aemilia, the temples of Julius and Vesta. Along one side the Sacra Via led to the Capitol (*q.v.*).

With the growth of the city other *fora* were added; the Forum Julium by Julius Caesar, the Forum Augustum, and the Forum Pacis, where Vespasian erected a temple of Peace, containing spoils from the temple of Jerusalem. The Forum Trajanum, erected by the emperor Trajan, surpassed all others in size and splendour, and remains the greatest monument of Roman architecture. Its most conspicuous feature was the column of Trajan, erected by the emperor in commemoration of his victories. See Rome.

**Forum Appii** (mod. Foro Appio). Ancient town of Latium, on the Appian Way (*q.v.*). It stood amid the Pontine Marshes, 42 m. S.E. of Rome, and near a canal which extended S. to near Terracina. The apostle Paul passed through the town on his way to Rome.

**Foscari, FRANCESCO** (1373-1457). Doge of Venice. After holding various offices in the republic he was elected doge in 1423. Ambitious to extend Venetian power, he took an active part in the politics of the mainland, entering a league against the Visconti of Milan in

1426, thereby acquiring Bergamo, Brescia, and Cremona. In 1441 Velaggio, Peschiera, and Lonato were added to the Venetian territories. The misdeeds of his son, Giacompo, brought about the doge's deposition, Oct. 24, 1457, and he died Nov. 1. Byron's tragedy, *The Two Foscari*, is founded on the

lives of Francesco and his son.

**Foscolo, Ugo** (1778-1827). Italian poet, romancer, and patriot. Born at Zante, Jan. 26, 1778, of

Venetian and Greek descent, and christened Niccolò, he changed his first name to Ugo. His story, *Lettere di Jacopo Ortis*, 1798, reflects the melancholy of the romantic period, and his best known poem, *I Sepolcri*, 1807, was inspired by the reverence due to the tomb and the immortality of the memories of the great. Foscolo served for a time in the French army, but, disillusioned as to Napoleon's intentions, sought refuge in England when the Austrians took Milan. He died at Turnham Green, Oct. 10, 1827. Buried at Chiswick, his remains were removed to Florence in 1871.

**Fossa** or **FOUSSA** (*Cryptoprocta ferox*). A carnivorous mammal, found only in Madagascar, and placed by most zoologists between the cat and the civet. It is about 5 ft. long, including the tail, which is nearly as long as the body. The fur is pale brown in colour, and the claws retractile like those of a cat.

**Fosse** (Lat. *fossa*, ditch). Excavation outside the ramparts or outer walls of a fort. Its purpose was to hinder the advance of an enemy, and make it impossible for him to find ground upon which to erect scaling ladders. Frequently filled with water, its effectiveness was also occasionally increased by its being planted with pointed stakes and palisades. Barbed wire entanglements may also be placed in it. See Castle; Fortification.

**Fosse Way.** Early English name for an ancient British highway from Axminster to Lincoln.

Ugo Foscolo,  
Italian poet

Francesco Foscari,  
Doge of Venice  
*After Gentile Bellini*

incorporated in the Romano-British road system, no part of its 182 m. deviates more than 6 m. from a straight line between these places. It runs through Bath, Cirencester, High Cross, and Leicester. Mentioned in an Anglo-Saxon charter, 744, it ranked as one of Edward the Confessor's four royal roads.

**Fossil** (Lat. *fossilis*, dug up). Term applied to organic remains whether plant or animal, or to direct evidence of their existence, preserved in any formation of the earth's crust, whether hard rock or superficial deposit. Fossils are not necessarily of great antiquity; bones of a sheep buried under recent flood deposits, as well as ancient organic remains, have been considered fossils. The term also includes the tracks of animals preserved in strata, such as dinosaur footprints, or other markings or impressions made by living creatures.

Fossilisation is the process of burial and subsequent preservation. The ultimate mode of

small. Few organisms remain buried for long without undergoing some chemical change; e.g. vegetable remains lose their volatile constituents, and a part of their carbon content remains as a thin film. The frozen mammoths of Siberia, however, with flesh and hair intact, are examples of preservation in an almost unchanged condition. Outlines of soft parts are sometimes preserved, like the impressions of wings of pterodactyls (winged reptiles) found in Bavaria; but shells, bones, and teeth are the most likely parts to be preserved.

Buried hard parts generally undergo petrification, i.e. solution of the original substance and its gradual replacement by mineral matter. Sometimes perfect details are preserved. Frequently the animal or plant is dissolved away and a cavity or mould is left in the enclosing rock. If the cavity is filled by infiltration of mineral matter a cast results. A hollow body such as a shell may become filled with material and, after solu-

far above sea level led the early Greek philosophers to invoke encroachments of the sea upon the land as an explanation. William Smith (the "father of English geology," 1769-1834) discovered that each member of a stratified series of rocks contained a definite assemblage of fossils, and that the same strata were always found in the same order of superposition. The essential value of fossils therefore is that they serve to distinguish individual horizons in a rock sequence.

For a long time all organic remains in rocks were attributed to the Noachian deluge, or to several such deluges, with successive special creations. But the great variety of fossils and their gradual progression from the earliest deposits to the present day gave the death-blow to this cataclysmal hypothesis, and led Darwin to propound his theory of evolution in 1859. Every plant and animal is found to possess a complicated history going far back into geological time, and the general succession of forms is consistent with slow evolution from simple to complex.

This evolutionary concept put new zest into palaeontology, the study of fossils, and led to detailed investigation of range, distribution, and lines of descent of fossil communities. This knowledge is being applied in the study of strata, or stratigraphy. Palaeontology, while remaining one of the highest branches of natural history, has important economic aspects. It is of fundamental importance in the search for oil, and in the correlation and investigation of coal seams. See *Evolution*; *Geology*; consult also *Invertebrate Palaeontology*, H. L. Hawkins, 1920; *Introduction to Palaeontology*, A. M. Davies, 1925; *Outlines of Palaeontology*, H. H. Swinerton, 2nd ed. 1930.

**Fossombrone.** City of Italy, in the prov. of Pesaro. The ancient Forum Sempronii, it stands on the Metauro 10 m. E.S.E. of Urbino. It has a castle and a cathedral rebuilt in the 18th century. There are silk factories and mineral springs. Ruins of the Roman city, destroyed by the Goths and Lombards, lie about 2 m. N.E. of the town, which had a bishop in the 6th century. In the Second Great War Fossombrone was overrun by the 8th army in late Aug., 1944; churches and secular buildings suffered a certain amount of damage; while three bridges were blown up by the Germans.

Fossil. 1. Skeleton of *Ichthyosaurus intermedius*, about 9 ft. long, Lower Lias, Somerset. 2. Slab of Lias shale, with remains of crinoid, *Pentacrinus hiermeri*, Württemberg. 3. Dragon fly, *Florissant*

occurrence of the fossil depends on such factors as the nature of the organism, its habitat and mode of life, the time and mode of burial, and events subsequent to its entombment. Fossilisation is achieved either by the checking of decomposition, or by the replacement of the hard parts of the body (bones, shell, etc.) by some relatively more durable substance; and it appears to be a lucky accident: the proportion of forms preserved to those lost is very

tion of the shell, an internal mould will occur in reversed relief, on which muscle impressions, etc., may be preserved.

Fossils have been known to exist in rocks since ancient times, but were first thought to be merely freak imitations of living forms. The identification of detailed structures in corresponding living and fossil forms led to the adoption of the view that they were relics of organisms once alive. The discovery of fossils in rocks

**Foster.** Name of a family of English cricketers. The sons of the Rev. Henry Foster, a master at Malvern College, they were there educated. Their names were H. K. Foster, Capt. W. L. Foster, D.S.O., who won this honour in Somaliland, R. E. Foster, B. S. Foster, G. N. Foster, and M. J. A. Foster. All played for Malvern and Worcestershire, which was sometimes called on this account Fostershire. H. K., R. E., and G. N. Foster gained their blues at Oxford.

Reginald (1878-1914) was the finest batsman and fieldsman of the brothers. At Lord's in 1900 he scored a century in each innings for the Gentlemen against the Players, and at Sydney in Dec., 1903, he scored 287 against Australia, a record for a test match until 1930. He died May 13, 1914. Basil (b. 1882) gained distinction as an actor and theatrical manager, specialising in comedy. Frank R. Foster (b. 1889), a great all-rounder who played cricket for England and captained Warwickshire, was no relation.

**Foster, JOHN** (1770-1843). British essayist. Born near Halifax, Sept. 17, 1770, the son of a yeoman weaver, he spent his early years at the loom. At 17 he joined the Baptists, and, after study at Brierly Hall and the Baptist College at Bristol, he took a pastorate at Newcastle-on-Tyne, 1792. In 1805 appeared his *Essays*, by which he is chiefly remembered. These, particularly that *On Decision of Character*, are distinguished by imagination, depth, eloquence, and sincerity. He died at Stapleton, near Bristol, Oct. 15, 1843.

John Foster,  
British essayist

**Foster, MYLES BIRKET** (1825-99). British artist. Born at North Shields, Feb. 4, 1825, of Quaker parentage, he studied under Ebenezer Landells, wood engraver, for whom he drew many illustrations on the blocks. Starting on his own account in 1846, he illustrated in black and white many poetical publications, and in 1859 turned to water-colour, painting

M. Birket Foster,  
British artist

especially idyllic landscapes in Surrey and other home counties. He became associate of the Royal Water Colour Society in 1860 and member in 1861. He died at Weybridge, March 27, 1899.

**Foster, STEPHEN COLLINS** (1826-64). American song writer. Born near Pittsburgh, July 4, 1826, he was chiefly self-taught as a musician. He graduated at Jefferson College, and from 1842 produced sentimental but memorable songs, mostly based on negro subjects and with words in negro dialect. These included *The Old Folks at Home*, *My Old Kentucky Home*, *Massa's in de Cold*, *Cold Ground*, *Old Black Joe*. The melodies are usually ascribed to Foster, but probably the words were adapted to suit the minstrel companies who first sang his songs. He died in New York, Jan. 13, 1864. *Memoirs* were published by his brother, Morison Foster, 1896, and H. V. Milligan, 1920.

**Fosterage.** Term used for the nursing and bringing-up of children by others than their parents. The custom prevailed in ancient Ireland, where the ties of fosterage were almost as close as those of blood relationship. Fosterage was undertaken either for payment or from affection, and lasted until the age of 13 for girls and 17 for boys. Apparently the mother paid for the fosterage of the boys and the father for that of the girls. A child was obliged to provide for the foster-parent in old age. *See* Family; Kinship.

**Fotheringhay.** A parish and village of Northamptonshire, England. It stands on the Nene, 4 m. N.E. of Oundle. Few traces remain of its 11th century castle, famous as the scene of the imprisonment, trial, and execution of Mary Queen of Scots in 1587, and as the birthplace of Richard III in 1452. Pop. 213.

**Foucault, LÉON** (1819-68). French physicist. Born Sept. 18, 1819, and educated privately, he became physicist to the Paris Observatory, where he constructed various instruments, of which the gyroscope and the polariser which bear his name were the most notable. He determined the relative velocities of light in air, in water, and in a vacuum and the existence of eddy currents in conductors in electro-magnetic fields; but is best remembered by "*Foucault's pendulum*." From the roof of the Panthéon in Paris he hung a pendulum 200 ft. long, free to oscillate in any direction. The pendulum never retraced its path,

but always deviated to the right, showing that the floor was moving and the earth rotating. Foucault died in Paris, Feb. 11, 1868. *Prom. Foo-co.*

**Foucault Currents.** Currents induced in solid iron cores by alternating current passing through coils wound thereon, and also by rotation in a magnetic field. *See* Electricity; Magnetism.

**Fouché, JOSEPH** (1759-1820). A French politician. Born near Nantes, May 21, 1759, he was educated by the Oratorians in Paris. Ordained priest, he became a teacher and rose to be principal of Nantes College in 1780. Throwing in his lot with the Revolution,

Joseph Fouché,  
French politician

he sat in the National Convention (1792), became a Jacobin, and vehemently advocated the execution of Louis XVI. Having renounced his orders, he was the moving spirit in the mummeries of the worship of reason and the spoliation of the churches.

Instrumental in the fall of Robespierre, 1794, Fouché became minister of police in 1799. Under Napoleon he retained this position, was raised to the senate, and, under the empire, was also minister of the interior. He was made duke of Otranto in 1808 and governor of Illyria in 1813. After Leipzig, seeing that Napoleon's power was on the wane, he prepared to desert to the Bourbons, under whom, after 1815, he again became minister of police. But he was exiled as a regicide in 1816, and died in Trieste, Dec. 25, 1820. It was Fouché who said of the murder of the duc d'Enghien, "It was worse than a crime; it was a blunder." *Consult* Life, S. Zweig, Eng. trans. 1930.

**Fougasse (Fr.)** Military mine originally placed under the glacis or ditch of a fortress. It is sometimes used to defend a defile or other approach by throwing a shower of stones upon the enemy. An excavation is made, the axis of which is inclined at an angle of about 40° to the horizon; it is about 4 ft. deep, in the form of a frustum of a cone, 5½ ft. at the surface. In a recess at the bottom is placed a square box of gunpowder, inclined to the horizon at 40°, and on the box a wooden shield about 6 ins. thick. The excavation is filled up with stones, the excavated

earth being placed in a mound in a line with the powder box to increase the resistance upwards, and so ensure the effect of the explosion upon the stones at the required angle; the fuse is led up from the box over the mound. The modern fougasse discharges burning oil, and the hedgehog fougasse can be concealed behind a wall or rise, over which it will jump on being fired.

**Fougasse.** Pseudonym of the humorous artist C. K. Bird (*q.v.*).

**Fougères.** Town of Brittany, France. It stands on the Nançon, in the dept. of Ille et Vilaine, 30 m. N.E. of Rennes. The chief buildings are the churches of S. Sulpice and S. Leonard, both of the 15th century, while there are remains of the castle and other fortifications built to protect the town in the Middle Ages. The castle, standing on a rock, was partially restored in the 20th century. Its eleven battlemented towers give an idea of its original size and strength. The hôtel de ville dates from the 15th century, and there are some old houses. The town is now a market for agricultural produce and a centre of tanning and other industries connected with the manufacture of boots and shoes. Granite is found in the vicinity. Fougères was long one of the strong places of Brittany, and was taken by the English in 1166 and 1448. In the Second Great War it was liberated by American armoured forces, Aug. 5, 1944. Pop. 19,281.

**Foula.** One of the Shetland Islands, Scotland. It lies 16 m. to the S.W. of the mainland, and is frequented by sea-fowl, the skua breeding here. It is a thriving fishing centre. Its length is  $3\frac{1}{2}$  m., breadth  $2\frac{1}{2}$  m., and highest point 1,370 ft.

**Foul Anchor.** Nautical term used to describe an anchor having one or both flukes entangled in the chain or rope. This is the device

Foul Anchor.  
Admiralty ensign

of the British Admiralty, the Admiralty flag being a yellow foul anchor on a red background.

**Foulard** (Fr.). Soft, thin, flexible fabric made of silk or silk and cotton, usually printed in colours on a light or dark ground, or having a white spot on a dark coloured ground.

The name was formerly applied to a gauze ribbon material manufactured in France.

Robert Foulis,  
Scottish publisher  
From a medallion by  
J. Tassie

in 1741. Two years later he was appointed printer to Glasgow university, and in 1744 took his brother Andrew (1712-76) into partnership. After the death of the two brothers the business was continued by Robert's son, Andrew (*d.* 1829).

The Foulis Press issued more than 550 vols., reprints of Greek, Latin, and British classics, remarkable for beauty of type, format, and textual accuracy. They included the "immaculate" Horace, 1744; the fine Homer, in four folio vols., 1756-58; a folio edition of Paradise Lost; and the poems of Gray and Pope. A collection of Foulis books is in the Mitchell Library, Glasgow. *Pron.* Fowls.

**Foulness.** Island and village of Essex, England. The island lies at the mouth of the Crouch, 7 m. N.E. of Shoeburyness, and is 5 m. in length by  $2\frac{1}{2}$  m. in breadth. It is protected from the sea by a dyke. The village church built in 1850 replaced a wooden structure. A replica of Hitler's West Wall was built on the island in 1943, and for months it was bombarded with experimental shells, rockets, and explosives. From the results of these experiments were devised the close-support weapons that breached the West Wall in France. Pop. 400.

**Foumart.** This is a contraction of foul marten, an old name for the polecat (*q.v.*).

**Foundation** (Lat. *fundare*, to lay the bottom of, found). Literally, the base of a building, or that upon which a structure rests. It is freely used, however, for a society, such as a college or school, hospital or monastery, which is endowed, and so founded or set up on a permanent basis. The money given for this purpose and the conditions for which the society exists are the foundation, the work of the founder.

Those on the foundation of a college at Oxford or Cambridge, or of a school such as Winchester and Eton, are those scholars and others who receive money from the college funds, under the conditions laid down by the statutes. Permanent charities, such as an alms-

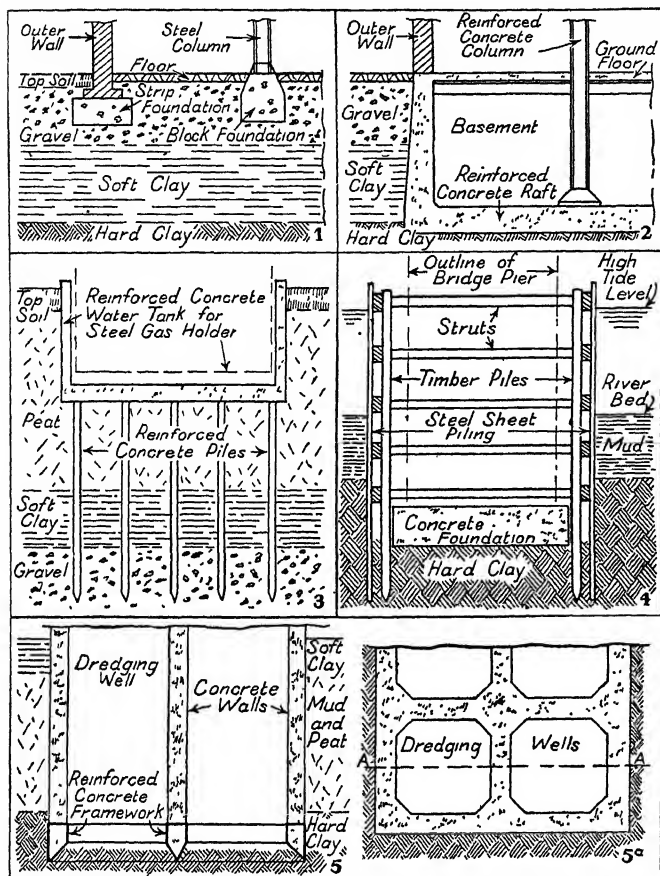

gow, April 20, 1707. While a barber's apprentice he attended the university lectures of Francis Hutcheson, on whose advice he started business as a printer and bookseller

house or a hospital, are also known as foundations, as are cathedrals. The chapters of the English cathedrals are divided into old foundations and new foundations. The former are those which were unchanged at the Reformation; the latter those which, being then composed of monks, were provided with new chapters. *See* Cathedral.

**Foundation.** That part of a building, bridge, or other structure which transfers the weight of the structure and the loadings imposed on it to the subsoil. The types of structures, the loadings thereon, and the types of subsoil on which structures can be built are widely variable, and the selection and design of suitable foundations requires the combination of theoretical and practical knowledge of construction with skill in design.

Subsoils include stiff river weed; waterlogged peat bogs; soft, medium, and stiff clays; running sand; moist or dry sand or gravel; chalk which may be as soft as mud or as hard as soft rock; and solid rock. Increasing knowledge of the strength and behaviour of these materials under load resulted in a new science of soil mechanics, the exponent of which was Prof. Karl Terzaghi. By using methods which he originated, it became possible to explain previously inexplicable failures, and to design foundations in difficult soils more economically and with a greater degree of confidence than formerly. These methods involve a thorough exploration of the subsoil by boreholes. Samples of the subsoil are taken at various depths and their strength is determined by laboratory methods. Clays are particularly troublesome; because of slow changes under load they may eventually fail after carrying the load of the structure safely for 100 years. The old Waterloo Bridge across the Thames failed partly for this reason.

**SHALLOW FOUNDATIONS.** Where the structure load per sq. ft. of foundation is small, as in houses, factories, and other buildings not more than four storeys high on good subsoil, shallow foundations, usually with strips and blocks of concrete under the walls and columns, are adopted. Failure may occur if there is a weak subsoil close below the foundations, as in Fig. 1. Other causes of failure are frost-heaving of silts and silty sands in winter, and shrinkage of clays in summer. Where strip and block foundations involve loading the subsoil too heavily, a concrete raft or a concrete box forming a

Foundation. Details of typical foundations. 1. Factory foundations on poor soil, liable to settle. 2. Reinforced concrete basement foundation. 3. Typical foundation supported on reinforced concrete piles. 4. Bridge foundation built in sheet piled cofferdam. 5. Reinforced concrete monolith foundation; showing section marked AA in 5a, which is a part sectional plan of the same foundation

basement to the building will spread the load (Fig. 2).

**PILED FOUNDATIONS.** If the upper subsoils are too weak to carry the structure loads, groups of piles founded at lower levels may be used (Fig. 3); but it is necessary to determine whether the lower subsoil can safely carry the ground above it as well as the structure load. Piles may be driven or formed in place.

**DEEP FOUNDATIONS IN COFFERDAMS.** Where the load per sq. ft. is high, and a suitable subsoil can be reached at a moderate depth, bridge piers in larger rivers and quay walls are frequently founded on large blocks of concrete formed in cofferdams. Sheet piling is driven to form a square or rectangle, and is then strutted with timber or steel (Fig. 4). The part of the piling in the clay forms a "cut-off" wall which prevents the water from percolating into the coffer-

dam, and the foundation is built under dry conditions after the water has been pumped out. This method was used for the second permanent Waterloo Bridge.

**WELLS AND CYLINDERS.** Where the load is not so heavy, or where the foundation is to be formed on land rather than through water and the upper subsoils are weak, well or cylinder foundations may be used. A framework of timber, steel work, or reinforced concrete is formed on the site of the foundation and walls of brickwork or concrete are built above it. The material inside the well is excavated, and the well structure sinks into the subsoil. Further walling is added and the process is repeated. Concrete or pig-iron may be piled on top of the walling to assist the well to sink to the correct level. When a suitable subsoil has been reached the well is pumped dry and filled with con-

crete. If it is desired to sink a cylinder foundation under "dry" conditions, and the ground water pressure is such that this cannot be done by ordinary means, air locks are fitted to the top of the cylinder and air is forced in under pressure to keep the water out, as in the diving bell. Men and materials enter the cylinder through the air lock, and when the outer door is shut the air pressure is increased to that inside the cylinder.

**MONOLITH FOUNDATIONS.** Monoliths are similar in structure to cylinder foundations, but are larger and usually square or rectangular. They are subdivided by two or more cross walls into a number of "wells" (Fig. 5) and sinking of the monolith is controlled by "grabbing" from the wells as necessary. The main towers of the recently completed Howrah Bridge, Calcutta—which was begun before the Second Great War and opened to traffic in 1943, and is a double cantilever steel structure of 1,500 ft. clear span—are founded on monoliths sunk over 100 ft. through soft clay and silt to hard clay. The monoliths are the largest and deepest ever used under similar conditions. Concrete floors were formed at foundation level, and the walls were left unfilled to reduce the weight on the clay. Reinforced concrete roofs were raised over the wells at ground level, and on these the bridge towers were successfully built.

**Foundation Day.** Public holiday observed in Australia on Jan. 26. It commemorates the anniversary of the first British settlement in Australia, when Capt. Arthur Phillip landed a party of convicts and marines on the shores of Sydney Cove, Port Jackson, New South Wales, Jan. 26, 1788.

**Foundation Garment.** Name given to a feminine garment designed to support the body without the help of whalebone or steel. The first garments of this kind were introduced in the 1890s and were of bodice type, giving support by the skill of their cut, by stitching, and by the use of two or more thicknesses of material at points of strain. The foundation garment did not achieve wide popularity, however, until the invention of a fine elastic yarn in 1930 made it possible to weave a firm yet yielding material with a two-way stretch, which was used wholly or in part to make pull-on and roll-on girdles and corsettes. With a girdle, which normally

reached little above the waist, a separate brassière was usually worn; this garment, designed to protect and support the bust as well as, where necessary, to improve its appearance, came into vogue after the high, rigid corset of the early years of the 20th century went out of fashion. Support for the bust, cut in brassière style, was incorporated in the corsetette. *See Corset.*

**Foundation Sacrifices.** Ritual immolation at the foundation of a building or settlement. Human skeletons are found beneath cornerstones in early Palestine, as at Gezer and Megiddo. When Mandalay was built, 1860, 52 human victims were buried alive. Legends of living burial are recorded of S. Columba's Cathedral, Iona; S. Patrick's monastery, Clonmacnoise. Animal bones were unearthed beneath old S. Paul's and Blackfriars Bridge, London. The Scandinavian kirk-grim was the spirit of the foundation victim. Animal slaughter as a foundation rite survives from W. Africa through Coptic Egypt and Muslim Syria to Borneo. The interment of statues in ancient Rome and effigies in medieval Europe points to an anterior custom of actual blood-shedding.

**Founder.** A disease affecting horses, cattle, sheep, and pigs. Known in veterinary science as laminitis, it is a painful inflammation of the laminae, or tissues connecting the hoof with the bones of the foot. It is caused by bad management and careless feeding, horses that have much corn and little exercise being apt to develop it suddenly. Indian corn, beans, peas, and barley undoubtedly predispose to this form of fever. In mares it may follow foaling. Treatment consists in a moderately strong purge and blood-letting, and frequent warm bran poultices. The animal may be slung, in order to take its weight off its feet, and if the pain is severe cocaine may be given.

**Founders' Company, THE.** London city livery company, to which ordinances were granted July 29, 1365.

It was formed to ensure that work by foundrymen in the city of London should be only with good metal. It was granted its present charter Sept. 18, 1614. Until 1908 the company had the power to size

and stamp brass weights in the City and 3 miles around. The hall is at 13, St. Swithin's Lane, E.C.; the former hall, still owned by the company, is in Lothbury and is occupied by Brown Shipley & Co., bankers. *Consult* History of the Founders' Company, N. N. Hibbert, 1925.

**Founder's Share.** Class of share granted to the originators of a joint stock company, or to others who have rendered services to it. They are usually few in number and for small amounts, 1s. perhaps; but sometimes they become valuable because they participate in the profits after a certain fixed amount has been reached. The fact that their total amount is small enables a successful business to pay an enormous percentage on such shares. This class of share is rarely issued now, and in some concerns those issued earlier have been bought out and cancelled. *See* Company Law.

**Foundling Hospital.** Charitable institution founded to prevent the murder or exposure of newly born children. Such institutions appear to have been coincident with the development of civilized society, and they undertake the education and training of children until the latter reach maturity. The first step towards avoiding the crime of child murder was the exposure or abandonment of an infant in a public place in the hope that it would be found (hence foundling) and cared for by someone other than the parents. The earliest recorded case of exposure seems to be that of Moses (Exodus 2). Foundlings thus exposed were assigned as property to those who took them under their protection, and provision was made in ancient Greece and Rome for the upbringing of unadopted infants at the expense of the state, an example followed by the French in 1790.

At Trèves cathedral, in the 6th century, foundlings were received and arrangements made for their care under the supervision of the archbishop. The first foundling hospital of which there is authentic record was at Milan towards the end of the 8th century. The Order of the Holy Ghost, founded at Montpellier in the 12th century, made the care of foundlings a special duty. The Spedale degli Innocenti, or Foundling Hospital, at Florence, dates from 1419-51. The Ospedale di S. Spirito, in Rome, founded by Innocent III, included a foundling institution. In 1536 Marguerite of Valois instituted a foundling hospital which was incor-

porated with the great Foundling Hospital in Paris, started in 1670. Foundling hospitals now exist in all the great capitals of the world, though the word foundling does not correctly describe them all.

One of the most interesting of such institutions was that in London. Its founder, Thomas Coram (1668-1751), a captain in the merchant service, and a man of comparatively humble means, advocated his project for nearly 20 years before, in 1739, it was realized. A house was taken in Hatton Garden and opened in 1741 for 20 infants. The later building in Guilford Street, Bloomsbury, dated from 1745, when it had 600 inmates, supported at an expenditure of five times the income. Parliament voted a grant of £10,000, but stipulated for indiscriminate admittance, which had to be abandoned. Since 1760 entry has been limited to illegitimate children who have been deserted by the father, but whose mothers can prove previous good character. Hogarth, one of the earliest governors, began an art exhibition in its rooms which led to the foundation of the annual exhibitions of the Royal Academy. Handel was another tireless benefactor, and from his day the hospital recorded a high musical reputation.

The Bloomsbury site was sold in 1926. The institution became known as the Thomas Coram Schools, Berkhamstead, whither it moved in 1935. *See* N.V.

**Foundry** (Lat. *fundere*, to pour, melt). Term properly referring to the art of casting molten metals into moulds; but more generally used for a building in which metals are founded. Metals have been melted and cast into moulds for over 5,000 years, and many examples of ancient Chinese, Japanese, and Roman castings may be seen in the museums of the world. From them may be obtained an idea of the growth of the art from single castings to modern castings weighing 100 tons or more and mass-produced articles weighing a fraction of an ounce. There are three main classes of foundry: ferrous (cast iron and steel); heavy non-ferrous (such as brass and bronze); and light metals (magnesium and aluminium alloys). But the methods used and principles applied are similar in all.

Essentially founding consists of making some form of patterned hole in sand and filling that hole with molten metal. When the metal cools it freezes, forming a solid replica of the shaped hole.

Founders' Company arms

ter Sept. 18, 1614. Until 1908 the company had the power to size

Further cooling causes contraction of the solid metal, so that the finished casting is slightly smaller than the hole; but otherwise the metal will have taken up the contours of the sand mould, which is then broken away from the casting. Engineers, metallurgists, physicists, chemists, and ceramists help to control and improve the processes, while melters, annealers, pattern- and core-makers are needed in every foundry.

The first item required before founding is a pattern of the same shape as the casting desired. This is prepared from a drawing of the component and may be made of wood, brass, cast iron, or white metal. Moulding technique must also be borne in mind, as the pattern has subsequently to be extracted from the sand without disturbing it. Yellow pine and mahogany are commonly used for wooden patterns. Cast iron is the most common metal used, though its weight sometimes makes it difficult to handle. Plaster of Paris is often used for small castings and for core patterns. Cores are those parts of the mould which must be made in separate sand shapes and assembled in the mould to produce hollows and undercut portions in the casting. Special sands make the moulds, and a great deal of experimental work has been carried out on them.

#### How to Make a Mould

The mould is made in several stages. A suitable moulding box is selected, and the top half is placed on a bench and filled with sand. The pattern is then pressed halfway into the sand, forming a temporary support for the bottom half, which is now placed on top and filled with sand. The boxes are then turned over and the temporary part is removed. The joint is covered with sand which contains no bonding agent, to prevent the two halves from sticking together. The procedure is repeated by putting the top half, or cope, on top and filling. The two halves may then be separated and the pattern removed. Feeders must then be formed to allow the metal to be poured in.

More complicated castings may need several mould boxes, with vents to hold the core in position when a hollow casting is to be made. When a core is used some outlet must be left, not only for the gases, but also for the core itself to be removed subsequently. Very large castings require pits and special structures; often loam, which contains more clay than

normal sands, is used for this work. A large casting may take several weeks to cool. For mass production most of the work of mould manufacture is carried out mechanically.

Furnaces used in foundries vary with the type of material being handled. They range from the huge open hearth and electric arc furnaces used for steel and the cupola for cast iron to the small electric induction and oil-fired furnaces of the non-ferrous industry. Techniques for handling the molten metal differ. Pipe castings are made in large quantities by centrifugal casting, in which the molten metal is thrown to the periphery of the mould by its own centrifugal momentum and solidifies there in an even layer. Die-casting employs metal moulds, which lend themselves to mass production. In general, cast metals are harder and more brittle than those that have been worked, but this result is often altered by heat treatment. See Casting; Furnace.

**Font.** In printing, a term for a supply of type of one size and face, with a distinctive nick. The quantity is ordered according to the number of compositors employed and the class of work for which it is required. For newspapers, an extra quantity of capitals and figures is necessary. With this proviso, a font will contain a standard number of all the letters of the alphabet, graded in bulk according to the occurrence of the letters in the language in which the type is cast. In the U.S.A. the word is spelt font. See Printing; Typefoundry.

**Fountain** (late Lat. *fontana*). Term applied to any construction for the supply of water, from a simple spring to an elaborate artificial basin with ornamental jets. The need of fountains was experienced in Oriental countries at a very early date. Traces of their employment have been found among the relics of the Chaldaean civilization; Pausanias mentions Hellenistic examples; and in ancient Rome they were fully developed as a means of distributing the water brought to the city by the aqueducts. Pliny the Elder notes the construction or repairing of more than 1,200 fountains in Rome alone.

The treatment of fountains was at first purely utilitarian. During the Renaissance, however, the ornate fountain was rapidly developed. The fountains of Berne, each dignified with a name of its own—The Bear, The Ogre, Justice—and the Fountain of the Innocents in Paris (dated 1550) are imposing

architectural structures. The common type of Renaissance fountain was a shallow basin, with a pillar of marble often surmounted by a statue of stone or bronze in the centre, from which projected jets that supplied the running water. The more primitive type was represented by the drinking fountains at street corners. In France, the zenith of fountain-construction was reached under Louis XIV; one may cite the elaborate fountains at Versailles, with their thousands of jets. When the practice of installing a water supply in individual houses was introduced towards the end of the 18th century, utilitarian fountains became rare. But bodies like the Metropolitan Drinking Fountain and Cattle Trough Association, formed in London in 1859, has proved that the demand for this type still exists. Notable ornamental fountains of modern times are the Fontana di Trevi at Rome, and those in the Place de la Concorde, Paris. The illumination of fountains by coloured flood-lighting has proved a popular practice.

**Fountain Pen.** Writing instrument with a reservoir of ink, contained in the hollow penholder, which automatically feeds the nib when the pen is in use, and is so controlled that the ink maintains a steady flow. The first fountain pen was introduced in England in 1835, but was not a success. But in 1884 L. E. Waterman patented his improved fountain pen, and his design continues to be the basis of most types.

The most important part of a fountain pen is the feed bar. A thin channel is grooved along the top of the feed and is in contact with the inner curve of the nib; in the channel are a number of capillary fissures which convey the ink from barrel to point of nib. A small valve in the neck of the barrel admits ink to the feed only when pressure is applied to the nib in the act of writing.

The barrel of the early fountain pen was devoted to the storage of ink, and was filled by means of a syringe. The first self-filling fountain pen had a flexible rubber sac inside the barrel, and attached to the feed assembly. On the outside of the barrel a lever was jointed to a thin strip of metal in contact with the sac; when the lever was raised, the strip of metal was pressed down against the sac, expelling the air. Upon the immersion of the point of the pen in ink, the lever was lowered and the pressure of the metal strip against the sac

1. Neptune fountain at Bologna, by Giovanni da Bologna, 1563-67. 2. Buffet cascade, Grand Trianon Gardens, Versailles, by Hardouin-Mansart, c. 1688. From an old painting. 3. Fountain of Falling Waters, Mexico City, 1755. 4. Fountain in Piazza Navona, Rome, by Bernini,

c. 1650. 5. Grande Cascade, St. Cloud, c. 1690. 6. Medina fountain, Naples, 17th cent. 7. Marble fountain in the gardens of the Paseo Colon, Buenos Aires. 8. Hercules fountain, Villa Reale di Castello, Florence, by N. Tribolo (1485-1550). 9. Basin of Apollo, Versailles, by Lebrun, c. 1680

**FOUNTAIN: ARTISTIC EXAMPLES FROM GREAT CITIES OF EUROPE AND AMERICA**

Fountain Pen. Fig. 1. Self-filling pen; a, plunger; b, diaphragm; c, breather tube; d, feed channel; e, barrel. Fig. 2. Pen with rotatable ball, a, instead of a nib; b, reservoir; c, adapter. Arrows show direction of ink flow

released, which then filled with ink by means of suction.

As the chemical constituents of ink corrode rubber, experiments were made to evolve a self-filling fountain pen which did not require a rubber sac. Sacless pens were provided with a piston in the base of the pen which pumped ink into the barrel. As the piston and sleeve were seldom sufficiently airtight, the pen either was not completely filled or else leaked. In 1932 a more efficient self-filler eliminated the ink sac or piston pump (Fig. 1). The pen was filled by pressing and depressing a plunger (a) which in turn caused a synthetic rubber diaphragm (b) to expand and contract. This forced air out of a breather tube (c) and created a vacuum, which drew ink through the feed channel (d) and into the barrel (e).

Barrels and parts are made of vulcanite or plastics, metals being avoided owing to their liability to corrosion. The nib is generally of gold tipped with iridium, the latter a metal least affected by ink.

A later type of fountain pen (Fig. 2) had a rotatable ball (a) in place of a nib. As the ball moved over the paper in the act of writing, its rotation drew ink from the reservoir (b) through the adapter (c). The ink had a high spirit content so that it dried immediately it reached the paper. When empty the pen was recharged with a fresh reservoir of the special ink required.

**Fountains Abbey.** A ruined abbey in the W. Riding of Yorkshire, England. It stands near the little river Skell, 3 m. S.W. of Ripon; it is in the grounds of the mansion of Studley Royal, while near it is a mansion dating from Stuart times, Fountains Hall. The ruins include those of the church with its tower, the former being 380 ft. long, the chapter house, 13th century choir, the magnificent cloisters, and other parts. They are perhaps the most complete in England and, with the possible exception of Tintern, the most beautifully situated. The abbey, a Cistercian house, was a long time in building. Begun about 1132 it was completed 200 years later. The monks came from S. Mary's Abbey, York. The house was dissolved by Henry VIII and the ruins and lands were sold. In the 18th century they were held by the Aislaby family of Studley Royal. In 1946 the Roman Catholic Church proposed to buy the abbey and restore part as a Benedictine monastery, setting up nine altars in memory of English-speaking nations allied in the Second Great War. See *illus. Abbey*, p. 7; *Cloister*, p. 2166.

**Fouqué, FRIEDRICH HEINRICH KARL, BARON DE LA MOTTE (1777-1843).** German author. Born at

Baron de la Motte Fouqué, German author

Brandenburg, Feb. 12, 1777, of Huguenot origin, he took part as a cavalry officer in the Prussian campaigns of 1794 and 1813, but literature occupied most of his time. For a while he was the most popular of German story-tellers, but his dependence upon the supernatural militated against a permanent popularity. He is chiefly remembered for his tale of *Undine*, 1811. He died in Berlin, Jan. 28, 1843.

**Fouquet, JEHAN (c. 1416-c. 1480).** A French painter, born at Tours. As a portrait painter he was patronised by Étienne Chevalier, treasurer of Charles VII and later of Louis XI. He was one of the greatest French primitives, his best-known works being a Bible, decorated with 150 miniatures, in the Bibliothèque Nationale in Paris; a *Book of Hours*; and nine miniatures of a manuscript of the *Antiquités des Juifs*. Unappreciated for 400 years, his work was displayed in Paris in 1904 and

recognized to be fundamental in the national art.

**Fouquet, NICOLAS, MARQUIS DE BELLE ISLE, VICOMTE DE MELUN ET DE VAUX (1615-80).** French statesman.

Nicolas Fouquet, French statesman

Born of a noble family in Paris, Jan. 27, 1615, he held posts in the parliament of Paris while still a youth, becoming procurator-general in 1650. In 1653 Mazarin made him superintendent of finances, and Fouquet used his position to make himself one of the wealthiest men in France. He worked to succeed Mazarin, 1661, as the king's chief minister, but Louis XIV, passed him over.

Fouquet built himself a luxurious palace at Vaux, entertaining lavishly and patronising the arts and letters. But Louis, exasperated by his long mismanagement of the finances and his overweening ambition, had him arrested at Nantes, Sept., 1661. His trial, 1661-64, notorious for its injustice, ended in his imprisonment for life at Pignerol, Piedmont, where he died, March 23, 1680. The theory that Fouquet was the Man in the Iron Mask (*q.v.*) has been proved untenable.

Charles Louis Auguste Fouquet (1684-1761), who conducted a masterly retreat from Prague in 1742 during the War of the Austrian Succession, was a grandson. *Pron. Fookay.*

**Fouquier-Tinville, ANTOINE QUENTIN (1747-95).** French Revolutionist. Born at Hérouel, Aisne,

A. Q. Fouquier-Tinville, French Revolutionist  
From a sketch

and trained for the law, he came to Paris and entered the secret police in 1783. A violent democrat, he joined the extremist party in the Revolution, and was appointed by Robespierre public prosecutor of the revolutionary tribunal, 1793. Utterly inhuman, he sent men and women of all ages and parties to the guillotine, Bailly, Danton, Robespierre, and St. Just amongst them, but in the reaction from the Reign of Terror he himself was guillotined on May 7, 1795.

**Fourberies de Scapin**, LES (The Tricks of Scapin). Three-act comedy by Molière. Derived partly from classical and partly from Italian sources, its scene is laid in Naples. Scapin, a servant, a character acted by the author, plays a series of tricks on two fathers, so that their sons may marry the two girls with whom they have fallen in love. The girls prove to be the brides whom the duped fathers had originally had in view.

The play, which has been described by Brander Matthews as a Punch-and-Judy piece for grown-ups, was first produced at the Palais-Royal, Paris, May 24, 1671. Otway wrote an English version, *The Cheats of Scapin*, 1677.

**Fourcroy**, ANTOINE FRANÇOIS (1755-1809). French chemist. Born in Paris, June 15, 1755, he was appointed in 1784 to the chair of chemistry at the Jardin du Roi. At the Revolution he became a member of the committee of public safety, and to his indifference is attributed the execution of Lavoisier. Among his discoveries are adipocere, cholesterol, the double salts of magnesium and ammonium, and pure baryta. He died Dec. 16, 1809.

**Four Freedoms**. Term used by the U.S. president F. D. Roosevelt in his message to congress on Jan. 6, 1941. Calling for a new order in international affairs, the president declared that the democratic ideal looked forward to a "world founded upon four essential human freedoms." These were freedom of speech and expression; freedom of every person to worship God in his own way; freedom from want—which meant economic understandings to secure to every nation a healthy peaceful life for its inhabitants; and freedom from fear—which meant a world-wide reduction of armaments so that no nation could commit any act of aggression against its neighbours. The four freedoms formed the basis of the charter of the United Nations drafted at San Francisco in 1945.

**Four Hundred**, TYRANNY OF THE. Oligarchy of nobles established in Athens for four months in 411 B.C. The prime author of the change of government was the exiled Alcibiades (*q.v.*), who knew he could not return to Athens so long as a democratic government was in power; the chief conspirator was Pisander. A reign of terror ensued and the Four Hundred made peace overtures to Sparta. The main Athenian army at Samos was furious, and the people at home, disgusted with the oppressive

measures and pro-Spartan sympathies of the Four Hundred, took matters into their own hands, and restored the democracy.

In 1890 Ward McAllister of New York happened to remark that about 400 people belonged to the best social circle in that city. The "four hundred" soon came into popular use to denote the smart set of any American city, whatever its supposed number.

**Fourier**, FRANÇOIS CHARLES MARIE (1772-1837). French Socialist. Born at Besançon, April 7,

F. C. Fourier,  
French Socialist

1772, the son of a well-to-do tradesman, having lost his inheritance in business, he served two years in the Revolutionary army, and then became a commercial traveller. He set himself to evolve a new social system in a series of works, the chief of which are *Theory of the Four Movements*, 1808, and *The New Industrial World*, 1829. He died Oct. 8, 1837.

Fourier's ideas attracted little attention during his lifetime, but were much discussed in the U.S.A., 1840-50. Several communities, notably those of Brook Farm (*q.v.*) and Red Bank, were established to put them into practice, but met with little success. Fourier's theory was that, man being essentially a gregarious animal, the population should be redistributed in a number of new social units, *phalanges*. Each *phalange* was to consist of 1,500 to 1,800 people, housed in a common building or *phalanstère*, with a square league of land attached; was to be industrially complete in itself and self-governing. Each worker was to receive a minimum wage, and the surplus was to be distributed thus: five-twelfths to labour, three-twelfths to talent, four-twelfths to capital.

**Fourier**, JEAN BAPTISTE JOSEPH (1768-1830). French mathematician and physicist. Born at Auxerre, March 21,

J. Baptiste Fourier,  
French mathematician

1768, he took an active part in the Revolution in that district. Later he accompanied Napoleon on his Egyptian expedition, and was made governor of

Lower Egypt. On his return to France he carried out experiments on the propagation of heat. His *Théorie Analytique de la Chaleur*, 1822, was based on Newton's Law of Cooling, and contains an account of the mathematical series (*v.i.*) by which he is chiefly remembered. Fourier died May 16, 1830.

**Fourier Series**. A trigonometrical series, involving sines and cosines of simple multiples of a variable which is restricted in possible value between definite limits. Such a series, named after J. B. J. Fourier, is of value in the solution of many problems in physics.

**Four Lakes**. Name given to a series of four lakes in Wisconsin, U.S.A. They are the Mendota, Monona, Waubesa, and Kegonsa, and are situated in the S. part of the state. Occupying an area of 225 sq. m., they are drained to the Rock river, by the Yahara river, and are navigable by steamers.

**Foursquare Gospellers**. Popular name for an evangelical religious sect, whose activities are described under *Elim Movement*.

**Fourteen Points**. Proposals made by President Wilson for the satisfactory conclusion of the First Great War. They were contained in an address to congress on Jan. 8, 1918, and in brief they were: (1) Open covenants of peace openly arrived at. (2) Freedom of the seas. (3) Removal of economic barriers between nations. (4) Guarantees that national armaments should be reduced to the lowest point consistent with domestic safety. (5) Adjustment of colonial claims upon the principle that the interests of the populations concerned must weigh equally with the claims of the government whose title to sovereignty was to be determined. (6) Evacuation of all Russian territory. (7) Evacuation and restoration of Belgium. (8) Freeing of all French territory, and of Alsace-Lorraine. (9) Readjustment of the frontiers of Italy along lines of nationality. (10) The peoples of Austria-Hungary to be accorded opportunity for autonomous development. (11) Evacuation and restoration of Rumania, Serbia, and Montenegro. (12) The Turkish portions of the Ottoman Empire to be assured a secure sovereignty, the other nationalities under Turkish rule to be given opportunity of autonomous development. (13) An independent Polish state, with access to the sea. (14) Formation of a league of nations.

The Fourteen Points were accepted in the autumn of 1918 by

the Central Powers when defeat was staring them in the face, and most of them were incorporated in the peace treaties. Later the Nazis maintained that the non-fulfilment of certain points, in particular No. 4, justified their repudiation of the Versailles settlement.

**Fourteenth Army.** A British formation of the Second Great War; the principal Allied fighting formation in the Burma campaign (*q.v.*). Its existence first became generally known on Jan. 11, 1944, though it had been formed three months previously from India's Eastern Army, after the retreat through Burma up to and beyond the Indian frontier, and its c.-in-c., Lt.-Gen. W. J. Slim (*q.v.*), was already planning to take the offensive under the orders of Gen. Sir George Giffard, c.-in-c. 11th army group. The army sign incorporated a sword, the hilt of which, S-shaped, was a reference to its commander's name. The high-level organization changed in Nov., 1944, when Lt.-Gen. Sir Oliver Leese arrived to take over Giffard's command, subsequently designated Alsea (Allied Land Forces, S.E. Asia).

Three Indian army corps were directly concerned in the Burma campaign—4th, 15th, and 33rd—and at various times 14 divisions served in Slim's command: 2nd and 36th British; 3rd (Chindits), 5th, 7th, 17th, 19th, 20th, 23rd, 25th, and 26th Indian; 11th East African; 81st and 82nd West African. In addition there were Burmese forces, Lushai brigade, Kachin Levies, and other irregulars, and the total man-power at one time reached over 1,000,000—the largest single army of the war, holding the longest front (from the Bay of Bengal to the Chinese border), and with perhaps the most varied composition.

Although British troops, principally infantry, formed one-third of each Indian division, and also provided the officers and n.c.o.s of the African formations, Indian, Gurkha, and African troops had a large share in the 14th army's remarkable history.

Air supply was gradually built up until the whole of the great force was being fed and equipped by "air-drop," the British, U.S., and Canadian transport squadrons concerned carrying on courageously even in the worst monsoon conditions. Close air support to forward troops and evacuation by air were extensively practised, and the army and air headquarters worked together as a team. In the

later stages, while the 4th and 33rd corps advanced through central Burma, the 15th, in Arakan, was detached under direct command of c.-in-c. Alsea, and the 36th division fought in the northern (U.S.-China) combat area.

After the reoccupation of Rangoon in May, 1945, 14th army H.Q. was moved back to India to direct the invasion of Malaya and the East Indies. A new Indian corps, the 34th, was destined as the spearhead of this operation. Following the establishment of his new H.Q. in Singapore in Sept., Gen. Slim handed over command to Gen. Sir Miles Dempsey (*q.v.*). On Dec. 1, 1945, the 14th army was disbanded. Official figures showed that, in its two years' existence, the 14th army had killed a total of 120,000 Japanese for a loss of only 17,000, despite a fanatical enemy, lack of equipment, appalling climate, and a heart-breaking terrain.

G. D. H. Linton

**Fourth.** Musical interval which includes four consecutive scale names, *e.g.* C, D, E, F. The interval between C and F is called a fourth, and as F is the fourth degree of the scale of C this is called a perfect fourth, and by some a major fourth. *See* Interval.

**Fourth Dimension.** (1) Term used in mathematics to express the degree of an item. Thus  $abcd$ ,  $a^4$ ,  $a^2b^2$ , are all of the fourth dimension or degree because they are products of four factors.

(2) A quantity is of the fourth dimension when its expression involves four fundamental measurements; *e.g.* the statement of the heat conductivity of a substance

needs four fundamental dimensions, mass, length, time, and temperature.

(3) The term has been used particularly in connexion with various systems of geometry, elaborated principally in the 19th century by Riemann, Cayley, Minkowski, and others. Some of these geometries incorporate time as an essential dimension of space (or space-time) and deny certain fundamentals of ordinary (or Euclidean) geometry, such as the ideas concerning parallel lines; others were based on the line as the unit measurement instead of the point; others attempted a spatial interpretation of relationships between lines, points, surfaces, and solids in theoretical space of  $n$  dimensions. These geometries helped greatly in the "geometrisation of physics" and the development by Einstein and others of the theory of relativity. *See* Mathematics. *Consult* also The Fourth Dimension, C. H. Hinton, 1904; Geometry of Time and Space, A. A. Robb, 1936; Physics and Experience, B. Russell, 1946.

**Fourth Estate.** Term sometimes applied to the press to emphasise its importance in the state, the three estates of the realm according to the constitution being the lords spiritual, lords temporal, and commons. The term was first used by Edmund Burke.

**Fourth of June.** Speech day and holiday at Eton College. The anniversary of the birthday of King George III is the principal celebration at Eton and is attended by boys' relatives and Old Etonians. In the morning a master calls "absence," when every boy must answer his name, this ceremony being followed by speeches

in Upper School. Cricket matches are played, and in the evening a firework display and a procession of decorated boats terminate the celebration.

**Fourth Party.** Name given about 1880 to a small independent and irresponsible body of Conservative politicians. The leading men were Lord Randolph Churchill, Sir H. Drummond Wolff, Sir John E. Gorst,

Fourth of June. "Absence" being called during the annual celebrations on this day at Eton College

and at times A. J. Balfour. Throughout the parliament of 1880-85 they frequently opposed and harassed the Conservative leader of the commons, Sir Stafford Northcote.

**Four-Year Plan.** Name given to two programmes of economic development in Nazi Germany. Hitler announced the first four-year plan in May, 1933—ostensibly a modest scheme for housing, road construction, and other public works. This work was executed, but served really as a façade behind which the rearming of Germany had begun. The second plan covered the years 1937-40 and was concerned with the development of substitute materials with a view to attaining self-sufficiency. It referred especially to oil from coal, synthetic rubber, artificial textiles, and the exploitation of Germany's ore reserves. Self-sufficiency had not been achieved in any field when Hitler launched the Second Great War in 1939.

**Fowey.** Seaport, market town, and watering place of Cornwall, England. It stands on the W. shore of the Fowey estuary, 10 m. S. by E. of Bodmin, on the railway. It has a fine harbour, formerly protected by three forts now in ruins, and is a favourite holiday resort and yachting station. A leading port in the Middle Ages, it supplied nearly 50 vessels for the blockade of Calais in 1346. There is a trade in china clay. Sir A. Quiller-Couch, long a resident, put Fowey into his novels as Troy Town. Market day, Sat. Pop. 2,382. *Pron.* Foy.

**Fowl** (A.S. *fugol*, bird). Name formerly meaning any bird, now applied to the various species of the genus *Gallus* of the pheasant family of the zoological order Gallinae, to which the game birds generally belong. Most of them have handsome plumage and strong legs, being better adapted for running than for flight. They range in size from the quail to the turkey, are mixed feeders, and are all valued for the table.

The many varieties of domestic fowl are certainly descended from the wild jungle fowl of India. The jungle fowl, which flourishes well in captivity, breeds freely with the domestic varieties, and the hybrids are always fertile. There is no record of the original domestication of the jungle fowl. It is possible that the bird was caught in greater numbers than were required for food at the moment, and that it was then found possible to keep it for a time in captivity, where it bred,

this suggesting a means of multiplying and maintaining a supply of food always at hand.

There is no trace of the fowl among the remains of birds and animals found in the kitchen middens of the Neolithic period, and it does not appear to have been known to the Greeks of the Homeric age. But it is mentioned in a Chinese encyclopedia compiled about 1400 B.C., though it is not clear if the wild or the domesticated bird is meant. There are, however, records in the code of Manu of cock-fighting in India about 1000 B.C., and this makes it probable—though not certain—that domestication had taken place at an earlier date. It is curious that the spread of the domesticated fowl westwards was due to the love of cock-fighting rather than to any appreciation of the value of the bird as an article of food. Aristotle in his *History of Animals* mentions the domestic fowl and gives various details of its habits and laying powers; but there is no mention of domestic fowls in the Old Testament of the Bible.

colour, but in only one way, namely, a brown cock crossed with a grey hen will produce grey male chicks and brown female chicks. No such differentiation occurs when a grey cock is crossed with a brown hen.

The best breed or strain varies with the purpose for which the bird is required—for egg production, for table quality, or for ornament. Egg production does not as a rule help the eating quality of the flesh, and breeding for eggs or meat will prevent ornamental development. Female birds up to twelve months old are called pullets, from 12 to 24 months yearlings, and only at 24 months old become hens. They begin to lay at five to six months.

Egg-producing birds tend to be small, seldom exceeding 7 lb. in weight. Average annual production of a good bird is 150-200 eggs. The Rhode Island Red, the Wyandotte, the Sussex, the Leghorn, and the Buff or Plymouth Rock are the principal laying breeds, and it is mainly with these breeds that experiments in crossing have been made.

Fowey. Picturesque seaport on the south Cornish coast, the "Troy Town" of "Q's" novels; it lies on the W. shore of the Fowey estuary

It is not known when the bird first reached Great Britain, the statement that it was brought by the Phoenicians being pure speculation. It is thought that the breed now known as Dorkings was introduced by the Romans, but here again decisive evidence is lacking. But cock-fighting was popular in Britain many centuries back, the earliest definite record dating from the reign of Henry II, when William FitzStephen wrote an account of the cock-fights that took place in schools on Shrove Tuesday.

Crossing between breeds of domesticated fowl has happened to such an extent that the parent breed is obscure. Sex is shown by

The pullet produced by crossing a Black Leghorn cock with a Rhode Island Red hen is black tinged with red and is an excellent layer, but the offspring of a Rhode Island Red crossed with a Light Sussex hen is a much better table bird.

The Rhode Island Red is usually chestnut in colour with yellow legs and orange eye. The Light Sussex is white with a black tail. Both are good table birds. The White Leghorn and the Black Leghorn are very good layers but poor table birds. The Buff Rock and the White Wyandotte are heavier birds and suitable for the table. Orpingtons, Minorcas, Brahmas, and Cornish are also

bred for the table, the first two being white skinned. See col. plates facing pp. 3496-97; also Poultry.

**Fowler, ALFRED** (1868-1940). British astronomer and spectroscopist. Born on March 22, 1868, in Yorkshire, he studied astrophysics at the Royal College of Science under Lockyer. On the removal of the Solar Physics Observatory to Cambridge in 1901, he was appointed assistant professor of astrophysics and founded at S. Kensington a unique laboratory in which the spectra of astronomical bodies were reproduced and identified. He took part in six eclipse expeditions, photographing for the first time the flash spectrum (*g.v.*) and making the first accurate measurements in the spectrum of the corona. His spectroscopic work formed the observational basis for Bohr's theory of atomic structure. Fowler was president of the Royal Astronomical Society, 1919-21, F.R.S. from 1910, and created C.B.E. in 1935. He died June 24, 1940.

**Fowler, ELLEN THORNEYCROFT** (1860-1929). British novelist. She was a daughter of the 1st Viscount Wolverhampton and married A. L. Felkin in 1903. She died June 21, 1929. Most of her stories, which include *Concerning Isabel Carnaby*, 1898; *A Double Thread*, 1899; *The Wisdom of Folly*, 1910, reflect life in the English Midlands under Methodist influence.

**Fowler, HENRY WATSON** (1858-1933). English lexicographer. He was born at Hinton St. George, Somerset, March 10, 1858, and became a master at Sedbergh in 1882. He retired in 1889 and lived quietly until 1915, when he joined the British army in France in his 57th year. At the end of the First Great War he returned to his researches and died Dec. 26, 1933.

Fowler was one of the most remarkable scholars of his day and had the ability to endow his pronouncements with persuasive charm and finality. At first in collaboration with his brother, F. G. Fowler, and later by himself he produced a series of textbooks which became oracles in the determination of correct English. A highly praised translation of Lucian appeared in 1905; *The King's English* in 1906. The brothers produced the *Concise Oxford Dictionary* in 1911, and after his brother had been killed, Henry continued the *Pocket Oxford Dictionary*. His supreme achievement was *A Dictionary of Modern*

English Usage, 1926. Two revealing books in 1929 were *If Wishes Were Horses*, and *Some Comparative Values*.

**Fowler, SIR JOHN** (1817-99). A British engineer. Born July 15, 1817, he became a civil engineer and was employed in railway schemes which accompanied the boom of 1846. Pimlico Bridge was built according to his designs in 1860. The same year he was engaged in the construction of the Metropolitan rly., opened 1863. In 1869 he was consulted by Ismail Pasha with regard to engineering schemes in Egypt. In 1883, in partnership with Benjamin Baker, he designed the Forth Bridge, which was opened in 1890. For this Fowler, who had been knighted in 1881, was made a baronet. He died March 27, 1899.

**Fowler, WILLIAM WARDE** (1847-1921). British scholar and ornithologist. Born May 16, 1847, son of a Swansea magistrate, he was elected to a fellowship at Lincoln College, Oxford, in 1872, becoming sub-rector ten years later. His volume on *Julius Caesar*, in 1892, was the first of a series of classical studies. His books on bird life added much to existing knowledge, the best known being *A Year with the Birds*. He died June 14, 1921. *A Life*, by R. H. Coon, appeared in 1934.

**Fowler-Dixon, JOHN EDWIN** (1850-1943). British athlete. Born Sept. 3, 1850, he devoted himself to athletics, and in 1877 won the 50 miles and the 100 miles amateur walking records. In 1884 and 1885 he created 50 miles running records of 6 hrs. 20 mins. 47 secs. and 6 hrs. 18 mins. 26 secs. respectively. In the former year he also made the 40 miles running record of 4 hrs. 46 mins. 54 secs., which had not been beaten when he died, Oct. 10, 1943. Proprietor of the *Athletic News*, he helped to found the Amateur Athletic Association, whose trophy for the two miles walk perpetuates his name.

**Fowler's Solution.** Popular name for *liquor arsenicalis*. It is a 1 p.c. solution of arsenious acid in water with small amounts of potassium carbonate and compound tincture of lavender, used occasionally in medicine, chiefly in morbid conditions of the blood.

**Fox.** Animal belonging to the genus *Vulpes*, probably consisting of only one species including several local races. It differs from dogs in the shape of its skull, and in the fact that the pupil of the eye is elliptical instead of circular. It is of slim build, with long bushy tail and rather long ears.

Foxes feed upon small mammals and birds, but also eat insects and fruit, feeding by night and spending the day in burrows, hollow trees, and clefts in rocks. They are found nearly everywhere throughout the northern hemisphere; and

the common fox (*Vulpes canis*) is a well-known inhabitant of Great Britain. It is reddish-brown in colour, with white beneath; but the hue varies considerably in local races, as in the so-called greyhound fox of the Lake District. It sometimes makes its own burrow, though it usually adapts that of the badger or rabbit.

In the summer it often sleeps in a dry ditch. The young, usually four or five in number, are born about April.

The fox is valued for its fur, especially that of the black and silver varieties. It is a favourite animal for hunting, but often works havoc in game preserve and poultry yard. It would have become extinct in Great Britain long ago but for its preservation by the hunts. See *Fur*.

**FOX OR KEENAH.** River of Wisconsin, U.S.A. Rising in the S. part of the state, it flows S.W. N., and N.E. to Lake Winnibago. Emerging from the N. end of that lake, it follows a N.W. course to Green Bay, a branch of Lake Michigan. In its upper reaches, near Portage, it is connected by a canal with Wisconsin river. It is 250 m. long, and navigable for most of its course.

**FOX OR PISHITAKA.** River of the U.S.A. Rising in Wisconsin, it flows 225 m. generally S. and S.W., and passes through Illinois to unite with the Illinois river at Ottawa.

**FOX.** Channel of N. America. It lies to the N. of Hudson Bay, separating Baffin Island on the E. from Melville Peninsula and Southampton Island on the W. It communicates by Hudson Strait with the Atlantic, and by Fury and Hecla Strait with the Arctic. Luke Fox, English navigator, explored it in 1631.

Fox. Common fox, *Vulpes canis*, emerging from its earth

**Fox, Sir Charles** (1810-74). British engineer. The son of Francis Fox, M.D., he was born at Derby, March 11, 1810. Having shown a distinct gift for mechanics, he was articled to an engineer, and was soon associated with Robert Stephenson and other pioneers of the steam engine. He did engineering work on various rlys., especially the London and Birmingham, and the firm of which he became a partner began to make rly. stock, introducing therein various improvements suggested by him. Fox built the Crystal Palace in Hyde Park and afterwards at Sydenham, and was very successful with his bridges. An enormous length of rly. line, almost in every part of the world, was undertaken by his firm, as well as tunnels, stations, among them Waterloo, Paddington, etc. In 1851 he was knighted. He died June 14, 1874, leaving his two elder sons to carry on the business of Sir Charles Fox & Sons.

**Fox, Sir Charles Douglas** (1840-1921). A British engineer. Born May 14, 1840, educated at Ch o l m o n d e l e y School and King's College, London, he joined his father, Sir Charles Fox, in business in 1861. Associated with him in railway and other engineering work, he soon came to the front. He was president of the Institute of Civil Engineers, and in 1886 was knighted. He died Nov. 13, 1921.

Sir C. Douglas Fox,  
British engineer  
Russell

A brother Francis (1844-1927) joined the firm 1861, being knighted in 1912. Sir Francis was called in to advise on the restoration of Winchester Cathedral, and was one of the experts consulted about the construction of the Simplon Tunnel. His published books include *The Mersey Tunnel* and *The Simplon Tunnel*. He died Jan. 7, 1927.

**Fox, Charles James** (1749-1806). British statesman. Born in London, Jan. 4, 1749, he was a younger son of Henry Fox, Lord Holland; his mother was a daughter of the duke of Richmond. He was educated at a school at Wandsworth, at Eton, and at Hertford College, Oxford. He read widely, and his industry, coupled with his great natural abilities, made him a scholar. In addition to a knowledge of the classics, he was a good French scholar and read Italian well. He was only a boy when,

*C. J. Fox*

(after Reynolds)

encouraged by his father, he began his career as a gambler and shared the other pleasures of his dissolute elders. In 1769 he entered parliament as M.P. for Midhurst, his father's pocket borough, and in 1770 he was made a junior lord of the admiralty under Lord North. In 1772 he resigned owing to his opposition to the court, but in 1773-74 he was again in office as a junior lord of the treasury.

Fox's career as a Whig leader may be dated from 1775. By then he had won the friendship of Burke, and had shown, in the case of the American colonies, for instance, that attachment to the cause of popular liberty which is the outstanding feature of his political career. He acted with the Whigs, then led by Lord Rockingham, but in many matters he was more advanced than they. His creed included parliamentary reform and purity in financial affairs, while, like many others, he saw a danger to the state in the undue influence of the crown. Soon came his advocacy of the repeal of Roman Catholic disabilities and of the causes of Ireland and the slave.

In 1782 Fox entered the cabinet of Lord Rockingham as secretary of state, but in a few months the premier died, and, refusing to serve under Lord Shelburne, he joined Burke and Sheridan in a Whig secession which in 1783 resulted in the extraordinary coalition between Fox and Lord North. In this the former was again a secretary of state, but this ministry had but a brief life. It was dismissed by the king as soon as the house of lords had rejected Fox's India Bill.

Fox, who in 1784 had fought at Westminster—for which constituency he had been first returned in 1780—one of the most fiercely con-

tested battles in electoral history, now appeared as a leading opponent of Pitt's ministry, although on some matters—the impeachment of Hastings, for instance—he was in agreement with the premier. In 1789 came his famous declaration of welcome to the French Revolution, an encomium on the fall of the Bastille, and in 1791 his long friendship with Burke came to an end on this issue. By 1792 the majority of the Whigs had ceased to hail the Revolution with rapture, regarding it rather as a tyranny; but Fox, almost alone, continued to support it. He declared against the war with France, but by now he had few followers, and after 1797 he ceased for a time to attend parliament. In 1798, for declaring publicly for the sovereignty of the people, his name was removed from the list of privy councillors.

About 1802 Fox returned to public life. He remained in opposition until the death of Pitt in 1806, when he again became a secretary of state, this time in the ministry of all the talents. He then endeavoured to negotiate a peace with France, but he soon realized that he had misread Napoleon's character. His health was already failing, and on Sept. 13, 1806, he died at Chiswick. He is buried in Westminster Abbey.

The vices and the virtues of Fox were both on the large scale. A leading member of the dissolute circle that surrounded the Prince Regent, he lost an ample fortune at cards, and was more than once bankrupt, dependent upon the charity of his friends. He showed, as did others, a lack of consistency between words and deeds, while he was capable of carrying his private animosities into public life. For constructive statesmanship he showed no ability whatever. On the other hand, he was a great orator and a greater debater. To the last his mind maintained its freshness by contact with the masterpieces of literature. He possessed a really generous nature, while his sympathy with the oppressed was the outcome of genuine feeling. He was long the idol of the Whigs, among whom his is undoubtedly the greatest name. In 1785 he married his mistress, Mrs. Armistead, and his later life was passed at St. Anne's Hill, near Chertsey. He began a life of James II, was something of a sportsman, and had fought a duel. See Pitt.

**Fox, Frederick** (1888-1945). British jockey. He served his apprenticeship with F. Pratt and rode his first winner at Warwick, April 8, 1907. He was champion jockey in 1930 with 129 winners, and Cameronian gave him his first success in the Derby in 1931. In 1935 Fox won the 2,000 Guineas and the Derby on Bahram, and rode as first jockey for George V, retiring at the end of 1936. He was killed in a motor accident, Dec. 12, 1945.

**Fox, George** (1624-91). Founder of the Society of Friends (*q.v.*). He was born at Drayton-in-the-Clay

George Fox,  
English Quaker

(now Fenny Drayton), Leicestershire, in July, 1624, son of Christopher Fox, a weaver, called by his neighbours "righteous Christer." His early bent towards religious

study suggested to his relatives that he should be made a priest. He was, however, apprenticed to a shoemaker and grazier in Nottingham. At the age of 19 he began a series of solitary wanderings in which he sought peace of mind from both churchmen and non-conformists, finally to decide that the one great qualification for the ministry was the presence of God in the heart—the inspiration of the Inward Light.

In 1648 he began to preach in public, adopting the terms "thee" and "thou," opposing many social conventions as well as ecclesiastical formalism, refusing to take oaths, condemning war, and advocating a rigid simplicity of dress. By 1658 communities of his followers were established in all parts of England. Founder and followers were, however, bitterly persecuted, Fox going to prison eight times. When in 1650 he bade the magistrates "tremble at the word of the Lord," he earned for his sect the nickname of Quakers.

In 1669 he married Margaret Fell, of Swarthmore Hall, widow of a judge and one of his early converts. He visited Scotland, 1657; Ireland, 1669; North America and the West Indies, 1671-72; and Holland, with Penn and Barclay, 1677 and 1684. Shortly after a meeting at the Friends' Meeting House, Gracechurch Street, Lon-

don, he died close by in White Hart Court, Jan. 13, 1691, and was interred in the Friends' Burial Ground, Bunhill Fields.

A man of sterling character whose practical gifts were displayed in the organization he gave to the society he founded, his voluminous writings are now seldom read, with the exception of his Journal, which, revised by a committee under the superintendence of Penn, first appeared in 1694. The MS. was sold at Sotheby's, July 26, 1920, for £1,750, and is now in the possession of the Society of Friends.

**Bibliography.** The Fells of Swarthmore Hall and Their Friends, M. Webb, 1865; Fox and the Early Quakers, A. C. Bickley, 1884; Life, T. Hodgkin, 1896; G. F., Seeker and Friend, R. M. Jones, 1930; The Personality of G. F., A. N. Brayshaw, now ed. 1933.

**Fox or Foxe, Richard** (c. 1448-1528). English statesman and prelate. Born at Ropesley, Lincs, the son of a yeoman, he was for periods at both Oxford and Cambridge. In 1485, in France, he entered the service of Henry VII. He began as the king's secretary, but was soon lord privy seal. Already ordained, and vicar of Stepney, he was made bishop of Exeter in 1487; in 1492 he was translated to Bath and Wells, and in 1494 to Durham. From 1501 until his death he was bishop of Winchester.

Fox was Henry's chief adviser, and most of the diplomatic work passed through his hands, including the momentous marriage and commercial treaties of this reign. Soon after the accession of Henry VIII, however, he lost his power. He was too steeped in the peaceful traditions of Henry VII to approve of the spirited foreign policy of the new era. Wolsey was too strong for him, and he resigned the privy seal in 1516. He died at Winchester, Oct. 5, 1528, being buried in the cathedral. Fox's great work was the foundation of Corpus Christi College, Oxford. At Cambridge he was chancellor and master of Pembroke Hall.

**Foxe, John** (1516-87). English martyrologist. Born at Boston, Lincs, and educated at Oxford, he was a fellow of Magdalen, 1539-45. He was a tutor in the Lucy family at Charlecote, and in the Howard family at Reigate. During Mary's reign he lived on the Continent, where he met Knox and other reformers, publishing in Latin at Strasbourg the first draft of his Acts and Monuments, familiarly known as Foxe's Book of Martyrs. On Elizabeth's accession Foxe

returned to England, was ordained priest by Grindal, lived in Grub Street, and worked on his Acts and Monuments, published in folio by John Daye, 1562-63. He became prebend of Salisbury and vicar of Skipton, 1563; and preached at Paul's Cross. He died April 18, 1587, and was buried at S. Giles's, Cripplegate. His principal work was a great favourite with Bunyan, greatly influenced the progress of Protestantism in England, and, although bitterly prejudiced, is an example of vivid prose.

John Foxe,  
English martyrologist

**Foxer.** Anti-submarine device used in the Second Great War. In 1943 German U-boats began firing a torpedo that could "home" on the noise of a ship's propeller and chase its victim before striking. A foxer was employed to upset the "brain" of this acoustic torpedo; a noise-maker which was towed astern of a ship and acted as a decoy. Not a single ship was sunk while using it.

**Foxglove.** Hardy biennial and perennial plants of the family Scrophulariaceae and genus *Digitalis*. Only one is a native of Great Britain, though there are a number of other species, the majority of botanical value only, which were introduced from Asia and Europe. Their height is from 2 ft. to 5 ft., and their flowers are purple, pink, white, yellow, or brown. They are raised from seed sown in gentle heat in May,

Foxglove. Flower  
of *Digitalis purpurea*

the plants being moved to the open air as soon as they are large enough to be shifted with safety. In sheltered shrubberies and copses a little seed may be sown annually. In mixed borders foxgloves should be placed at the back, in associa-

tion with delphiniums, hollyhocks, sunflowers, and other tall-growing subjects. The wild purple foxglove of our lanes and woods is *D. purpurea*. See Digitalis.

**Foxhound.** Breed of hound specially maintained for hunting the fox. Of mixed origin, it is generally believed to be descended from the old type of bloodhound and the pointer, with perhaps a dash of the bulldog strain. Fox-hunting dates from the days of Edward I, but the dogs then used were entirely different from the present breed of hounds, which is probably not more than 300 years old. The breed has received much attention, and such packs as the Belvoir and the Quorn are of world-wide fame.

The foxhound is notable for its speed and endurance, having been known to follow the fox for ten hours. A good foxhound should stand about 24 ins. high at the shoulder, but the females are usually 3 ins. shorter. The head should be large and full, the nostrils wide open. The short, rounded shape of the ear is the result of cropping when a puppy, and is intended to prevent the ears from being torn when going through thick cover. The back and shoulders should be strong and muscular, the hind quarters well formed, and the legs straight. The coat, always parti-coloured, should be short, thick, and smooth. See Dog.

**Foxhunting.** Sport of the English countryside in which a fox is hunted, with intent to kill, by the aid of a pack of specially bred and trained hounds called foxhounds. Probably the Bilsdale in Yorkshire (the duke of Buckingham, circa 1670) and the South and West Wilts (Lord Arundell of Wardour, 1690-1700) are the oldest packs of foxhounds. In the early days of foxhunting, great landowners kept packs of hounds, their kennels being moved from place to place, which hunted over immense areas, later hunted by several recognized packs. Hunting was a slow and laborious process, the foxhunter starting at daybreak and laying his hounds on to the drag of the fox which was then hunted steadily up to where he had laid up for the day. Roused, the fox was then worn down in a long and slow hunt of many hours. An increase of pace began in the Quorn country about 1750 under the aegis of Hugo Meynell, and also in the Pytchley, then controlled by the Lord Spencer of the day. Hounds began to be bred for speed, and the thoroughbred

was introduced into the hunting-field, an innovation not favoured even as late as the 1840s. A hundred years later the half-bred horse was commonly ridden.

With the enclosure of common lands, jumping became fashionable, and others besides the rural population became interested. The repeal of the corn laws, causing the change of so many tilled fields to pasture—particularly in the Midlands where the fashionable packs are to be found—was a final factor which encouraged speed. The heyday of fast hunting

Foxhound. Hound from the kennels of the Oakley foxhounds

in "the shires" was from the 1870s until the First Great War, when a very fast horse which could jump whatever in reason came in its way was essential to the ambitious follower of the hunt.

Long hunts were still not uncommon even as the pace increased, and points (i.e. the farthest straight distance from "find" to "kill") of anything up to ten miles were frequently made, while the distance "as hounds ran" was nearly always very much more, all covered at a good gallop. Such achievements were possible only through the improvement in staying power of hounds brought about by careful breeding.

The old slow tactics, however, disappeared, and the fox was killed as much by pace as by the actual hunting of his line. Thus for many of the field, hunting became a matter of hard riding rather than of vengery.

Twentieth century hunting is something between the two. Less damage is done, and large "fields" out solely for the ride, many of them in no way connected with the land over which they ride, are not so usual. The establishment of aerodromes, the enclosure of land occupied by T.T. herds, more tillage, and an increase of wire everywhere, leave plenty of scope for foxhunting, but make the old hard riding impossible.

The nature of a hunt depends in general upon the character of the

country in which it takes place. A well-wooded country, with coverts close to one another, provides the best scope for hound work, whilst open land with some distance between coverts gives most chance of a good gallop. There are approximately 200 packs of hounds in Great Britain today recognized by the Master of Foxhounds association, which is the governing body, establishing boundaries, and laying down rules for the conduct of the chase. Only the master of a pack recognized by the association may place the initials M.F.H. after his name. The Quorn, Pytchley, Belvoir, Fernie's, and Cottesmore are usually known as "the Shires," and fall into the "open country" category, but many provincial packs come very near to the same description. Well known hunts famed for good hunting, and many of them covering both kinds of country, include The Duke of Beaufort's (a very large country centred round Badminton); the Warwickshire; the Bicester, Grafton, and Whaddon Chase in the home counties; the York and Ainsty (two packs); Cheshire; and Blackmore Vale in Dorset and Somerset.

Riding to hounds is only a part of the enjoyment to many who are interested in watching the work of hounds and huntsman in overcoming the wiles of probably the cleverest of all eluders. A good huntsman knows his country and has a very good idea of the probable line his hunted fox will take, where it is likely to be found initially, and how to keep with his hounds so as to be at hand should they require his assistance. He will also know when to leave them alone. His hounds are individuals to him and he appreciates and relies upon the individual quality of each. Some hounds are particularly expert on a cold and stale scent, some are distinguished by the determination with which they penetrate the thickest cover; some are "babblers," other only "speak" when they are sure. It is in watching the handling of this diverse team that the enthusiastic foxhunter gets a great deal of his pleasure.

The cost of hunting is met by those who hunt, by those who, while not hunting themselves, yet take an interest in and subscribe to, their local pack, and, in increasing numbers, by the farmers over whose land the hunt passes. Farmers are in general staunch

foxhunters, assisting hunt establishments in kind (in the form of forage for hunt horses or dead stock for hounds) as well as with subscriptions, and getting wire taken down wherever possible during the hunting season. Indeed, the survival of the fox depends upon the good will towards the chase of the rural population in general.

The Master of a pack of hounds undertakes to hunt the country so many days a week with a certain subscription, making up the balance as may be required himself. Prior to 1939 the cost of hunting a country was estimated at £1,000 per annum for each day in the week hunted, i.e. a four days a week country cost £4,000 a year. When hunting was renewed at the end of the Second Great War costs had risen by at least 50 p.c. Control of a country by a committee has tided many packs over emergencies such as inability to find a Master. Committees are, however, never more than stop-gaps; individual leadership is essential to the well-being of a country. The money provided is spent on wages for the huntsman (unless the Master hunts hounds himself), one or two whippers-in, at least two more men in stables to ride "2nd horse" at meet, a stud groom, kennel man, one or two feeders (according to the number of hounds kept in kennel, anything from 20-75 couple), and payment to earth stoppers, those who seal up the fox-earths in the night whilst the foxes are out, so that the hunted fox shall not find refuge underground if it can be prevented—an onerous task if properly performed. Oatmeal and flesh for hounds, and fodder for hunt horses, have to be found; compensation claims for damaged fences or the loss of poultry taken by foxes have to be met. Hunt servants' livery is another item, and saddlery for hunt horses.

Foxhunting encourages the breeding of the English hunter—a type of horse eagerly sought after all over the world. Hound-breeding is almost an industry, and the British foxhound is perhaps the greatest triumph of dog-breeding in the world. Evolved from a deer-hunting dog, the foxhound will hunt deer, fox, hare, or otter according to training. There are many breeds of hound hunting by scent in Europe and America, but the English type leads them all and is always saleable abroad.

1920; Hunting the Fox, Lord Willoughby de Broke, 1920; Wild Lone, "B.B.," 1938.

**Fox Islands.** Variant name given to the Aleutian Islands (*q.v.*). It is more specifically confined to the extreme E. group, consisting of Unalaska, Unimak, Umnak, and a number of smaller islands.

**Fox Land.** Desolate region in the S.W. of Baffin Island, British N. America. It lies between Fox Channel on the N.W. and Hudson Strait on the S.E.

**Foxtail.** Means of preventing a bar of wood or metal bolt from being withdrawn from a hole. The entering end is split, the point of a wedge is inserted, and the bar is driven home, the wedge expanding the material against the sides of the hole.

**Foxtail Grass** (*Alopecurus pratensis*). Perennial grass of the family Gramineae. It is a native of Europe, N. Africa, and Asia. It sends out runners from the roots, and has flowering stems 1 ft. to 3 ft. high. The leaves are rough and flat; the flowers form a soft, cylindric panicle. It is a most valuable meadow-grass, and of high nutritive value.

**Fox Terrier.** Small breed of terrier, of two types, the smooth-haired and the wire-haired or rough-coated. The smooth-haired is used in the hunt for unearthing

Fox Terrier. Prizewinning dog of the rough coated variety

foxes and the rough-haired for rattling. Either is a popular domestic pet on account of its intelligence, friendly disposition, and readiness to obey orders. To judge from show records, the smooth-haired fox terrier came into favour earlier than the rough-coated, though the latter is the better hunter. In everything except coat, the two varieties are identical. In colour the fox terrier should be black, white, and tan; specimens that show liver-coloured markings should be avoided for show and breeding purposes. See Dog and illus. on colour plate.

**Foxtrot.** Dance of American origin from negro sources. As a comparatively simple social dance for two partners, based on an adaptation of the march step to ragtime rhythm, it rapidly became popular in every part of the world from 1914, replacing the waltz as the most frequent item in "ballroom" dance programmes. Later it became more of a generic term for a style of dance than the name of any particular sequence of movements. Foxtrots may be either fast (quickstep) or slow (approximating to the Blues), simple or complex. See Dancing, Ballroom.

**Foy, MAXIMILIEN SÉBASTIEN** (1775-1825). French soldier. Entering the army in 1791, he first saw service under Dumouriez. Distinguishing himself in Italy, 1801, and in the Austrian campaign, 1805, he was sent by Napoleon in 1807 with a small force to

Maximilien Foy, French soldier

the sultan against the Russians and British. In 1808 he was in Spain, and fought in the Peninsular War, being made a divisional general in 1810. He held a command at Waterloo. After 1815 he made his peace with the new regime and sat in the French chamber. He died in Paris, Nov. 28, 1825. His History of the Peninsular War was published in 1827.

**Foyers.** Two cascades (40 ft. and 165 ft.) near the mouth of the Foyers river, on the E. side of Loch Ness, Inverness-shire, Scotland. Since 1895 they have been used by the British Aluminium Company for generating electricity.

**Foyle.** Lough or inlet between co. Donegal, Eire, and co. Londonderry, N. Ireland, into which drains the river Foyle, 16 m. long. It is 18 m. long and has a width of 1 m. at the entrance, and an extreme width of 10 m. Dangerous shoals obstruct navigation on the W. side.

**Foynes.** Village of co. Limerick, Eire, 24 m. W. of Limerick, at the estuary of the Shannon. Here was established the first eastern base, for flying boats only, for trans-Atlantic flights. It came into use in 1937, first for trials and later for regular services, by British and U.S. aircraft. It afterwards became part of the Shannon airport (*q.v.*) with Rineanna, 8 m. distant, the main landplane terminal.
